        rev: master
```

The playbooks modules also includes the ability to specify a git repo to clone and use, or a specific directory can to used when running the playbook.

Network Automation

Beginning with this release, Salt provides much broader support for a variety of network operating systems, and features for configuration manipulation or operational command execution.

NetBox

Added in the previous release, 2018.3.0, the capabilities of the `netbox` Execution Module have been extended, with a much longer list of available features:

- `netbox.create_circuit`
- `netbox.create_circuit_provider`
- `netbox.create_circuit_termination`
- `netbox.create_circuit_type`
- `netbox.create_device`
- `netbox.create_device_role`
- `netbox.create_device_type`
- `netbox.create_interface`
- `netbox.create_interface_connection`
- `netbox.create_inventory_item`
- `netbox.create_ipaddress`
- `netbox.create_manufacturer`
- `netbox.create_platform`
- `netbox.create_site`
- `netbox.delete_interface`
- `netbox.delete_inventory_item`
- `netbox.delete_ipaddress`
- `netbox.get_circuit_provider`
- `netbox.get_interfaces`
- `netbox.get_ipaddresses`
- `netbox.make_interface_child`
- `netbox.make_interface_lag`
- `netbox.openconfig_interfaces`
- `netbox.openconfig_lacp`
- `netbox.update_device`
- `netbox.update_interface`

Besides this Execution Module, Salt users can load data directly from NetBox into the device Pillar, via the `netbox` External Pillar module.

Netmiko

Netmiko, the multi-vendor library to simplify Paramiko SSH connections to network devices, is now officially integrated into Salt. The network community can use it via the *netmiko* Proxy Module or directly from any Salt Minions, passing the connection credentials - see the documentation for the *netmiko* Execution Module.

Arista

Arista switches can now be managed running under the *pyeapi* Proxy Module, and execute RPC requests via the *pyeapi* Execution Module.

Cisco Nexus

While support for SSH-based operations has been added in the release codename Carbon (2016.11), the new *nxos_api* Proxy Module and *nxos_api* allow management of Cisco Nexus switches via the NX-API.

It is important to note that these modules don't have third party dependencies, therefore they can be used straight away from any Salt Minion. This also means that the user may be able to install the regular Salt Minion on the Nexus switch directly and manage the network devices like a regular server.

General-purpose Modules

The new *ciscoconfparse* Execution Module can be used for basic configuration parsing, audit or validation for a variety of network platforms having Cisco IOS style configuration (one space indentation), as well as brace-delimited configuration style.

The *iosconfig* can be used for various configuration manipulation for Cisco IOS style configuration, such as: *configuration cleanup*, *tree representation of the config*, etc.

NAPALM

Commit At and Commit Confirmed

Beginning with this release, NAPALM users are able to execute scheduled commits (broadly known as "commit at") and "commit confirmed" (revert the configuration change unless the user confirms by running another command). These features are available via the `commit_in`, `commit_at`, `revert_in`, or `revert_at` arguments for the *net.load_config* and *net.load_template* execution functions, or *netconfig.managed*.

The counterpart execution functions *net.confirm_commit*, or *net.cancel_commit*, as well as the State functions *netconfig.commit_cancelled*, or *netconfig.commit_confirmed* can be used to confirm or cancel a commit.

Please note that the commit confirmed and commit cancelled functionalities are available for any platform whether the network devices supports the features natively or not. However, be cautious and make sure you read and understand the caveats before using them in production.

Multiple Templates Rendered Simultaneously

The `template_name` argument of the *net.load_template* Execution and *netconfig.managed* State function now supports a list of templates. This is particularly useful when a very large Jinja template is split into multiple smaller and easier to read templates that can eventually be reused in other States. For example, the following syntax is not correct to manage the configuration of NTP and BGP simultaneously, using two different templates and changing the device configuration through one single commit:

```
manage_bgp_and_ntp:
  netconfig.managed:
    - template_name:
        - salt://templates/bgp.jinja
        - salt://templates/ntp.jinja
    - context:
        bpg: {{ pillar.bgp }}
        ntp: {{ pillar.ntp }}
```

Connection Re-establishment on Demand

Beginning with this release, any NAPALM command executed when running under a NAPALM Proxy Minion supports the `force_reconnect` magic argument.

Proxy Minions generally establish a connection with the remote network device at the time of the Minion startup and that connection is going to be used forever.

If one would need to execute a command on the device but is connecting using different parameters (due to various causes, e.g., unable to authenticate the user specified in the Pillar as the authentication system - say TACACS+ is not available, or the DNS resolver is currently down and would like to temporarily use the IP address instead, etc.), it implies updating the Pillar data and restarting the Proxy Minion process restart. In particular cases like that, you can pass the `force_reconnect=True` keyword argument, together with the alternative connection details, to enforce the command to be executed over a separate connection.

For example, if the usual command is `salt '*' net.arp`, you can use the following to connect using a different username instead:

```
salt '*' net.arp username=my-alt-usr force_reconnect=True
```

The same goes with any of the other configuration arguments required for the NAPALM connection - see *NAPALM proxy documentation*.

Configuration Replace Features

To replace various configuration chunks, you can use the new *net.replace_pattern* execution function, or the *netconfig.replace_pattern* State function. For example, if you want to update your configuration and rename a BGP policy referenced in many places, you can do so by running:

```
salt '*' net.replace_pattern OLD-POLICY-CONFIG new-policy-config
```

Similarly, you can also replace entire configuration blocks using the *net.blockreplace* function.

Configuration Save Features

The *net.save_config* function can be used to save the configuration of the managed device into a file. For the State subsystem, the *netconfig.saved* function has been added which provides a complete list of facilities when managing the target file where the configuration of the network device can be saved.

For example, backup the running configuration of each device under its own directory tree:

```
/var/backups/{{ opts.id }}/running.cfg:
  netconfig.saved:
    - source: running
    - makedirs: true
```

All the new network automation modules mentioned above are directly exposed to the NAPALM users, without requiring any architectural changes, just eventually install some requirements:

Junos

The features from the existing *junos* Execution Module are available via the following functions:

- *napalm.junos_cli*: Execute a CLI command and return the output as text or Python dictionary.
- *napalm.junos_rpc*: Execute an RPC request on the remote Junos device, and return the result as a Python dictionary, easy to digest and manipulate.
- *napalm.junos_install_os*: Install the given image on the device.
- *napalm.junos_facts*: The complete list of Junos facts collected by the `junos-eznc` underlying library.

Note: To be able to use these features, you muse ensure that you meet the requirements for the *junos* module. As `junos-eznc` is already a dependency of NAPALM, you will only have to install `jxmlease`.

Usage examples:

```
salt '*' napalm.junos_cli 'show arp' format=xml
salt '*' napalm.junos_rpc get-interface-information
```

Netmiko

The features from the newly added *netmiko* Execution Module are available as:

- *napalm.netmiko_commands*: Execute one or more commands to be execute on the remote device, via Netmiko, and return the output as a text.
- *napalm.netmiko_config*: Load a list of configuration command on the remote device, via Netmiko. The commands can equally be loaded from a local or remote path, and passed through Salt's template rendering pipeline (by default using `Jinja` as the template rendering engine).

Usage examples:

```
salt '*' napalm.netmiko_commands 'show version' 'show interfaces'
salt '*' napalm.netmiko_config config_file=https://bit.ly/2sgljCB
```

Arista pyeapi

For various operations and various extension modules, the following features have been added to gate functionality from the *pyeapi* module:

- *napalm.pyeapi_run_commands*: Execute a list of commands on the Arista switch, via the `pyeapi` library.

- *napalm.pyeapi_config*: Configure the Arista switch with the specified commands, via the `pyeapi` Python library. Similarly to *napalm.netmiko_config*, you can use both local and remote files, with or without templating.

Usage examples:

```
salt '*' napalm.pyeapi_run_commands 'show version' 'show interfaces'
salt '*' napalm.pyeapi_config config_file=salt://path/to/template.jinja
```

Cisco NX-API

In the exact same way as above, the user has absolute control by using the following primitives to manage Cisco Nexus switches via the NX-API:

- *napalm.nxos_api_show*: Execute one or more show (non-configuration) commands, and return the output as plain text or Python dictionary.
- *napalm.nxos_api_rpc*: Execute arbitrary RPC requests via the Nexus API.
- *napalm.nxos_api_config*: Configures the Nexus switch with the specified commands, via the NX-API. The commands can be loaded from the command line, or a local or remote file, eventually rendered using the templating engine of choice (default: `jinja`).

Usage examples:

```
salt '*' napalm.nxos_api_show 'show bgp sessions' 'show processes' raw_text=False
```

Ciscoconfparse

The following list of function may be handy when manipulating Cisco IOS or Junos style configurations:

- *napalm.config_filter_lines*: Return a list of detailed matches, for the configuration blocks (parent-child relationship) whose parent and children respect the regular expressions provided.
- *napalm.config_find_lines*: Return the configuration lines that match the regular expression provided.
- *napalm.config_lines_w_child*: Return the configuration lines that match a regular expression, having child lines matching the child regular expression.
- *napalm.config_lines_wo_child*: Return the configuration lines that match a regular expression, that don't have child lines matching the child regular expression.

Note: These functions require the `ciscoconfparse` Python library to be installed.

Usage example (find interfaces that are administratively shut down):

```
salt '*' napalm.config_lines_w_child 'interface' 'shutdown'
```

IOSConfig

For Cisco IOS style configuration, the following features have been added to the *napalm* Execution Module:

- *napalm.config_tree*: Transform Cisco IOS style configuration to structured Python dictionary, using the configuration of the interrogated network device.

- *napalm.config_merge_tree*: Return the merge tree of the configuration of the managed network device with a different configuration to be merged with (without actually loading any changes on the device).
- *napalm.config_merge_text*: Return the merge result (as text) of the configuration of the managed network device with a different configuration to be merged with.
- *napalm.config_merge_diff*: Return the merge diff after merging the configuration of the managed network device with a different configuration (without actually loading any changes on the device).

SCP

Reusing the already available connection credentials provided for NAPALM, the following features are now available:

- *napalm.scp_put*: Transfer files and directories to remote network device.
- *napalm.scp_get*: Transfer files and directories from remote network device to the localhost of the Minion.

PeeringDB

The *peeringdb* Execution Module is useful to gather information about other networks you can potentially peer with, and automatically establish BGP sessions, e.g., given just a specific AS number, the rest of the data (i.e., IP addresses, locations where the remote network is available, etc.) is retrieved from PeeringDB, and the session configuration is automated with minimal to no effort (typing the IP addresses manually can be both tedious and error prone).

New Docker Proxy Minion

Docker containers can now be treated as actual minions without installing salt in the container, using the new `docker proxy minion`.

This proxy minion uses the *docker executor* to pass commands to the docker container using *docker.call*. Any state module calls are passed through the corresponding function from the *docker* module.

```
proxy:
  proxytype: docker
  name: keen_proskuriakova
```

Terraform Salt-SSH Roster

You can now dynamically generate a Salt-SSH roster from the terraform resources defined with terraform-provider-salt.

This allows you to combine both terraform and Salt-SSH to provision and configure your hosts. See the *terraform roster* for an example on how to setup and use.

Grains Dictionary Passed into Custom Grains

Starting in this release, if a custom grains function accepts a variable named `grains`, the Grains dictionary of the already compiled grains will be passed in. Because of the non-deterministic order that grains are rendered in, the only grains that can be relied upon to be passed in are `core.py` grains, since those are compiled first.

More Precise `virtual` Grain

This release improves the accuracy of the `virtual` grain when running Salt in a nested virtualization environment (e.g. `systemd-nspawn` container inside a VM) and having `virt-what` installed.

Until now, the `virtual` grain was determined by matching against all output lines of `virt-what` instead of individual items which could lead to not quite precise results (e.g. reporting `HyperV` inside a `systemd-nspawn` container running within a Hyper-V-based VM.

Configurable Module Environment

Salt modules (states, execution modules, returners, etc.) now can have custom environment variables applied when running shell commands. This can be configured by setting a `system-environment` key either in Grains or Pillar. The syntax is as follows:

```
system-environment:
  <type>
    <module>:
      # Namespace for all functions in the module
      _:
        <key>: <value>

      # Namespace only for particular function in the module
      <function>:
        <key>: <value>
```

- `<type>` would be the type of module (i.e. `states`, `modules`, etc.).
- `<module>` would be the module's name.

> **Note:** The module name can be either the virtual name (e.g. `pkg`), or the physical name (e.g. `yumpkg`).

- `<function>` would be the function name within that module. To apply environment variables to *all* functions in a given module, use an underscore (i.e. `_`) as the function name. For example, to set the same environment variable for all package management functions, the following could be used:

```
system-environment:
  modules:
    pkg:
      _:
        SOMETHING: for_all
```

To set an environment variable in `pkg.install` only:

```
system-environment:
  modules:
    pkg:
      install:
        LC_ALL: en_GB.UTF-8
```

To set the same variable but only for SUSE minions (which use zypper for package management):

```
system-environment:
  modules:
    zypper:
```

(continues on next page)

(continued from previous page)

```
      install:
        LC_ALL: en_GB.UTF-8
```

Note: This is not supported throughout Salt; the module must explicitly support this feature (though this may change in the future). As of this release, the only modules which support this are the following `pkg` virtual modules:

- *`aptpkg`*
- *`yumpkg`*
- `zypper`

"Virtual Package" Support Dropped for APT

In APT, some packages have an associated list of packages which they provide. This allows one to do things like run `apt-get install foo` when the real package name is `foo1.0`, and get the right package installed.

Salt has traditionally designated as "virtual packages" those which are provided by an installed package, but for which there is no real package by that name installed. Given the above example, if one were to run a *`pkg.installed`* state for a package named `foo`, then *`pkg.list_pkgs`* would show a package version of simply `1` for package `foo`, denoting that it is a virtual package.

However, while this makes certain aspects of package management convenient, there are issues with this approach that make relying on "virtual packages" problematic. For instance, Ubuntu has four different mutually-conflicting packages for `nginx`:

- nginx-core
- nginx-full
- nginx-light
- nginx-extras

All four of these provide `nginx`. Yet there is an nginx package as well, which has no actual content and merely has dependencies on any one of the above four packages. If one used `nginx` in a *`pkg.installed`* state, and none of the above four packages were installed, then the nginx metapackage would be installed, which would pull in *nginx-core_*. Later, if `nginx` were used in a *`pkg.removed`* state, the nginx metapackage would be removed, leaving nginx-core installed. The result would be that, since *nginx-core_* provides *nginx_*, Salt would now see nginx as an installed virtual package, and the *`pkg.removed`* state would fail. Moreover, *nginx would not actually have been removed*, since nginx-core would remain installed.

Starting with this release, Salt will no longer support using "virtual package" names in `pkg` states, and package names will need to be specified using the proper package name. The *`pkg.list_repo_pkgs`* function can be used to find matching package names in the repositories, given a package name (or glob):

```
# salt myminion pkg.list_repo_pkgs 'nginx*'
myminion:

Alternatively, the newly-added *pkg.show* function can be used to get more detailed information about a given package and help determine what package name is correct:

```
# salt myminion pkg.show 'nginx*' filter=description,provides
myminion:

Minion Startup Events

When a minion starts up it sends a notification on the event bus with a tag that looks like this: `salt/minion/<minion_id>/start`. For historical reasons the minion also sends a similar event with an event tag like this: `minion_start`. This duplication can cause a lot of clutter on the event bus when there are many minions. Set `enable_legacy_startup_events: False` in the minion config to ensure only the `salt/minion/<minion_id>/start` events are sent.

The new *`enable_legacy_startup_events`* minion config option defaults to `True`, but will be set to default to `False` beginning with the Sodium release of Salt.

The Salt Syndic currently sends an old style `syndic_start` event as well. The syndic respects *`enable_legacy_startup_events`* as well.

Failhard changes

It is now possible to override a global failhard setting with a state-level failhard setting. This is most useful in case where global failhard is set to `True` and you want the execution not to stop for a specific state that could fail, by setting the state level failhard to `False`. This also allows for the use of `onfail*`-requisites, which would previously be ignored when a global failhard was set to `True`. This is a deviation from previous behavior, where the global failhard setting always resulted in an immediate stop whenever any state failed (regardless of whether the failing state had a failhard setting of its own, or whether any `onfail*`-requisites were used).

Pass Through Options to `file.serialize` State

This allows for more granular control over the way in which the dataset is serialized. See the documentation for the new `serializer_opts` and `deserializer_opts` options in the *`file.serialize`* state for more information.

`file.patch` State Rewritten

The `file.patch` state has been rewritten with several new features:

- Patch sources can now be remote files instead of only `salt://` URLs
- Multi-file patches are now supported
- Patch files can be templated

In addition, it is no longer necessary to specify what the hash of the patched file should be.

New no_proxy Minion Configuration

Pass a list of hosts using the `no_proxy` minion config option to bypass an HTTP proxy.

Note: This key does nothing unless proxy_host is configured and it does not support any kind of wildcards.

```
no_proxy: [ '127.0.0.1', 'foo.tld' ]
```

Changes to `slack` Engine

The output returned to Slack from functions run using this engine is now formatted using that function's proper outputter. Earlier releases would format the output in YAML for all functions except for when states were run.

Enhancements to `wtmp` Beacon

A new key, `action`, has been added to the events fired by this beacon, which will contain either the string `login` or `logout`. This will simplify reactors which use this beacon's data, as it will no longer be necessary to check the integer value of the `type` key to know whether the event is a login or logout.

Additionally, in the event that your platform has a non-standard `utmp.h`, you can now configure which type numbers indicate a login and logout.

See the *wtmp beacon documentation* for more information.

Deprecated and Removed Options

API Removed Arguments

Support for *LocalClient*'s `expr_form` argument has been removed. Please use `tgt_type` instead. This change was made due to numerous reports of confusion among community members, since the targeting method is published to minions as `tgt_type`, and appears as `tgt_type` in the job cache as well.

Those who are using the *LocalClient* (either directly, or implicitly via a *netapi module*) need to update their code to use `tgt_type`.

```
>>> import salt.client
>>> local = salt.client.LocalClient()
>>> local.cmd('*', 'cmd.run', ['whoami'], tgt_type='glob')
{'jerry': 'root'}
```

Minion Configuration Deprecated Option

The *master_shuffle* configuration option is deprecated as of the `2019.2.0` release. Please use the *random_master* option instead.

Module Removed Options

- The *napalm_network* module has been changed as follows:
    - Support for the `template_path` has been removed from *net.load_template* function. This is because support for NAPALM native templates has been dropped.
- The *pip* module has been changed as follows:
    - Support for the `no_chown` option has been removed from *pip.install* function.
- The *trafficserver* module has been changed as follows:
    - The `trafficserver.match_var` function was removed. Please use *trafficserver.match_metric* instead.
    - The `trafficserver.read_var` function was removed. Please use *trafficserver.read_config* instead.
    - The `trafficserver.set_var` function was removed. Please use *trafficserver.set_config* instead.
- The `win_update` module has been removed. It has been replaced by *win_wua*.
- The *win_wua* module has been changed as follows:

    - The `win_wua.download_update` and `win_wua.download_updates` functions have been removed. Please use *win_wua.download* instead.
    - The `win_wua.install_update` and `win_wua.install_updates` functions have been removed. Please use *win_wua.install* instead.
    - The `win_wua.list_update` function has been removed. Please use functions have been removed. Please use *win_wua.get* instead.
    - The `win_wua.list_updates` function has been removed. Please use functions have been removed. Please use `win_wua.list` instead.

Pillar Removed Option

- The *vault* external pillar has been changed as follows:
    - Support for the `profile` argument was removed. Any options passed up until and following the first `path=` are discarded.

Roster Removed Option

- The *cache* roster has been changed as follows:
    - Support for `roster_order` as a list or tuple has been removed. As of the `2019.2.0` release, `roster_order` must be a dictionary.
    - The `roster_order` option now includes IPv6 in addition to IPv4 for the `private`, `public`, `global` or `local` settings. The syntax for these settings has changed to `ipv4-*` or `ipv6-*`, respectively.

State Removed Modules and Options

- The `docker` state module has been removed
    - In *2017.7.0*, the states from this module were split into four separate state modules:
        - *docker_container*
        - *docker_image*
        - *docker_volume*
        - *docker_network*
    - The `docker` module remained, for backward-compatibility, but it has now been removed. Please update SLS files to use the new state names:
        - `docker.running` => *docker_container.running*
        - `docker.stopped` => *docker_container.stopped*
        - `docker.absent` => *docker_container.absent*
        - `docker.network_present` => *docker_network.present*
        - `docker.network_absent` => *docker_network.absent*
        - `docker.image_present` => *docker_image.present*
        - `docker.image_absent` => *docker_image.absent*
        - `docker.volume_present` => *docker_volume.present*

    - `docker.volume_absent` => *docker_volume.absent*

- The *docker_network* state module has been changed as follows:
  - The `driver` option has been removed from *docker_network.absent*. It had no functionality, as the state simply deletes the specified network name if it exists.
- The deprecated `ref` option has been removed from the *git.detached* state. Please use `rev` instead.
- The `k8s` state module has been removed in favor of the *kubernetes* state mdoule. Please update SLS files as follows:
  - In place of `k8s.label_present`, use *kubernetes.node_label_present*
  - In place of `k8s.label_absent`, use *kubernetes.node_label_absent*
  - In place of `k8s.label_folder_absent`, use *kubernetes.node_label_folder_absent*
- Support for the `template_path` option in the `netconfig.managed <salt.states.netconfig.managed()` state has been removed. This is because support for NAPALM native templates has been dropped.
- Support for the `no_chown` option in the `pip.insalled` state has been removed.
- The `trafficserver.set_var` state has been removed. Please use *trafficserver.config* instead.
- Support for the `no_chown` option in the :py:func'virtualenv.managed <salt.states.virtualenv.managed>' function has been removed.
- The `win_update` state module has been removed. It has been replaced by *win_wua*.
- Support for virtual packages has been removed from the py:mod:*pkg state <salt.states.pkg>*.

Utils Removed Options

The `cloud` utils module had the following changes:

- Support for the `cache_nodes_ip` function in `salt utils module` has been removed. The function was incomplete and non-functional.

The `vault` utils module had the following changes:

- Support for specifying Vault connection data within a 'profile' has been removed. Please see the *vault execution module* documentation for details on the new configuration schema.

Dependency Deprecations

Salt-Cloud has been updated to use the `pypsexec` Python library instead of the `winexe` executable. Both `winexe` and `pypsexec` run remote commands against Windows OSes. Since `winexe` is not packaged for every system, it has been deprecated in favor of `pypsexec`.

Salt-Cloud has deprecated the use `impacket` in favor of `smbprotocol`. This changes was made because `impacket` is not compatible with Python 3.

SaltSSH Major Updates

SaltSSH now works across different major Python versions. Python 2.7 ~ Python 3.x are now supported transparently. Requirement is, however, that the SaltMaster should have installed Salt, including all related dependencies for Python 2 and Python 3. Everything needs to be importable from the respective Python environment.

SaltSSH can bundle up an arbitrary version of Salt. If there would be an old box for example, running an outdated and unsupported Python 2.6, it is still possible from a SaltMaster with Python 3.5 or newer to access it. This feature requires an additional configuration in /etc/salt/master as follows:

```
ssh_ext_alternatives:
    2016.3:                      # Namespace, can be actually anything.
        py-version: [2, 6]       # Constraint to specific interpreter version
        path: /opt/2016.3/salt  # Main Salt installation
        dependencies:            # List of dependencies and their installation paths
          jinja2: /opt/jinja2
          yaml: /opt/yaml
          tornado: /opt/tornado
          msgpack: /opt/msgpack
          certifi: /opt/certifi
          singledispatch: /opt/singledispatch.py
          singledispatch_helpers: /opt/singledispatch_helpers.py
          markupsafe: /opt/markupsafe
          backports_abc: /opt/backports_abc.py
```

It is also possible to use several alternative versions of Salt. You can for instance generate a minimal tarball using runners and include that. But this is only possible, when such specific Salt version is also available on the Master machine, although does not need to be directly installed together with the older Python interpreter.

SaltSSH now support private key's passphrase. You can configure it by:

- *–priv-passwd* for salt-ssh cli
- *salt_priv_passwd* for salt master configure file
- *priv_passwd* for salt roster file

State Module Changes

`salt` State Module (used in orchestration)

The `test` option now defaults to None. A value of `True` or `False` set here is passed to the state being run and can be used to override a `test: True` option set in the minion's config file. In previous releases the minion's config option would take precedence and it would be impossible to run an orchestration on a minion with test mode set to True in the config file.

If a minion is not in permanent test mode due to the config file and the 'test' argument here is left as None then a value of `test=True` on the command-line is passed correctly to the minion to run an orchestration in test mode. At present it is not possible to pass `test=False` on the command-line to override a minion in permanent test mode and so the `test: False` option must still be set in the orchestration file.

`event.send` State

The *`event.send`* state does not know the results of the sent event, so returns changed every state run. It can now be set to return changed or unchanged.

`influxdb_user.present` Influxdb User Module State

The `password` parameter has been changed to `passwd` to remove the name collusion with the influxdb client configuration (`client_kwargs`) allowing management of users when authentication is enabled on the influxdb instance

Old behavior:

```
influxdb_user.present:
  - name: exampleuser
  - password: exampleuserpassword
  - user: admin
  - password: adminpassword
```

New behavior:

```
influxdb_user.present:
  - name: exampleuser
  - passwd: exampleuserpassword
  - user: admin
  - password: adminpassword
```

`winrepo_cache_expire_min` Windows Package Definitions Caching

The *`winrepo_cache_expire_min`* has been changed from 0 to 1800 (30 minutes) For example if you run highstate the package definitions are normally updated, however now if the package definitions are younger than *`winrepo_cache_expire_min`* (30 minutes) the package definitions will not be refreshed, reducing the amount of time taken to run a 2nd highstate. To get the old behaviour change the value back to 0 in the minion configuration file. This also effects the behaviour of other functions which default to refresh. The `pkg.refresh_db` will always refresh the package definitions.

LDAP External Authentication

freeipa `groupattribute` support

Previously, if Salt was using external authentication against a freeipa LDAP system it could only search for users via the `accountattributename` field. This release add an additional search using the `groupattribute` field as well. The original `accountattributename` search is done first then the `groupattribute` allowing for backward compatibility with previous Salt releases.

Jinja Include Relative Paths

When a jinja include template name begins with `./` or `../` then the import will be relative to the importing file.

Prior practices required the following construct:

```
{% from tpldir ~ '/foo' import bar %}
```

A more "natural" construct is now supported:

```
{% from './foo' import bar %}
```

Comparatively when importing from a parent directory - prior practice:

```
{% from tpldir ~ '/../foo' import bar %}
```

New style for including from a parent directory:

```
{% from '../foo' import bar %}
```

salt-api

salt-api Windows support

Previously, salt-api was was not supported on the Microsoft Windows platforms. Now it is! salt-api provides a RESTful interface to a running Salt system. It allows for viewing minions, runners, and jobs as well as running execution modules and runners of a running Salt system through a REST API that returns JSON. See *Salt-API* documentation. .. _Salt-API: https://docs.saltstack.com/en/latest/topics/netapi/index.html

Logging Changes

Include Job ID (JID) in Minion and Master Logs

The Job ID (JID) can now be optionally included in both the minion and master logs by including `jid` in either the `log_fmt_console` or `log_fmt_logfile` configuration option:

```
log_fmt_console: "[%(levelname)-8s] %(jid)s %(message)s"
```

The will cause the JID to be included in any log entries that are related to a particular Salt job. The JID will be included using the default format, `[JID: %(jid)s]` but can be overriden with the `log_fmt_jid` configuration item.

```
log_fmt_jid: "[JID: %(jid)s]"
```

Security

Windows runas changes

A password is no longer required with `runas` under normal circumstances. The password option is only needed if the minion process is run under a restricted (non-administrator) account. In the aforementioned case, a password is only required when using the `runas` argument to run command as a different user.

28.2.6 Salt 2019.2.1 Release Notes

Version 2019.2.1 is a bugfix release for *2019.2.0*.

Known Issues

- **ISSUE** #54751: Proxy minion fails to start. Fix planned in 2019.2.2 release.
- **ISSUE** #54762: URIs with IPv6 addresses are broken, preventing master-minion communication in IPv6-only environments. Fix planned in 2019.2.2 release.
- **ISSUE** #54776: Minion fails to start when it contains *ping_interval* in minion configuration file. Fix planned in 2019.2.2 release.
- **ISSUE** #54731: Returners (except for default salt master returner) not loading properly in Py3. Fix planned in 2019.2.2 release.
- **ISSUE** #54758: salt-call state.show_states gives "Passed invalid arguments" error when a sls defined in top.sls file is missing. Fix planned in 2019.2.2 release.
- **ISSUE** #54765: Jinja from import is broken. Fix planned in 2019.2.2 release.
- **ISSUE** #54771: Affects only Debian 10. pkgrepo.managed does not work if used with proxy (configured at salt-minion). No fix date available yet.
- **ISSUE** #54759: Deprecation warnings for pyzmq. No fix date available yet.

Change to YAML Renderer

```
/etc/foo.conf:
  file.managed:
    - source: salt://foo.conf.jinja
    - template: jinja
    - context:
        data: {{ data }}
```

In 2019.2.0, the above SLS will result in an error message following changes to the YAML renderer that now require the new Jinja filter *tojson*.

```
/etc/foo.conf:
  file.managed:
    - source: salt://foo.conf.jinja
    - template: jinja
    - context:
        data: {{ data|tojson }}
```

In 2019.2.1, we introduce a new configuration option for both the Salt master and Salt minion configurations to be able to support the older YAML renderer. Using the option `use_yamlloader_old` will allow the YAML renderer to function as before.

  - a2173d7 Fixing a typo where attempting to get a list from __opts__ instead of an individual item
  - 6a5b5b2 swapping out if…else approach for __opts__.get approach.
  - aa2c626 With the change/addition of the matcher subsystem in 2019.2, the match.search_by when used in pillar broke when targetting the minion that was also the salt master. This was caused by the id in __opts__ being used in all cases. This change updates the glob_match function to use the preserved minion_id of the master if it is available so that targeting works as expected.

28.2.8 Salt 2019.2.3 Release Notes

Version 2019.2.3 is a CVE-fix release for *2019.2.0*.

Security Fix

CVE-2019-17361

With the Salt NetAPI enabled in addition to having a SSH roster defined, unauthenticated access is possible when specifying the client as SSH. Additionally, when the raw_shell option is specified any arbitrary command may be run on the Salt master when specifying SSH options.

28.2.9 Salt 2019.2.4 Release Notes

Version 2019.2.4 is a CVE-fix release for *2019.2.0*.

Security Fix

CVE-2020-11651

An issue was discovered in SaltStack Salt before 2019.2.4 and 3000 before 3000.2. The salt-master process ClearFuncs class does not properly validate method calls. This allows a remote user to access some methods without authentication. These methods can be used to retrieve user tokens from the salt master and/or run arbitrary commands on salt minions.

CVE-2020-11652

An issue was discovered in SaltStack Salt before 2019.2.4 and 3000 before 3000.2. The salt-master process ClearFuncs class allows access to some methods that improperly sanitize paths. These methods allow arbitrary directory access to authenticated users.

Known Issue

Part of the fix for CVE-2020-11651 added better validation of the methods allowed to be called by remote clients. Both AESFuncs and ClearFuncs now have an explicit list of methods that can be called. The name of one of these whitlisted methods on AESFuncs had a typo. The _minion_runner method should be minion_runner (without the underscore prefix). This typo breaks the publish module's runner method. Calling runners, for example:

```
salt minion publish.runner manage.down
```

Will not work, and you will receive and empty reply from the salt master.

This will be addressed in the Sodium release of Salt set for mid-June 2020.

28.2.10 Salt 2019.2.5 Release Notes

28.2.11 Salt 2018.3.0 Release Notes - Codename Oxygen

Warning: If you are using Jinja to dump lists or dictionaries in your SLS files, this will now cause errors in Python 2 since Jinja does not produce YAML-compatible output when strings in the data structures contain unicode types. The dictionary must be passed through a Jinja filter to produce YAML-compatible strings.

The below is an example of invalid SLS:

```
/etc/foo.conf:
  file.mangaged:
    - source: salt://foo.conf
    - template: jinja
    - defaults: {{ mydict }}
```

To make it valid, use either one of Salt's own `json` or `yaml` filters:

```
/etc/foo.conf:
  file.mangaged:
    - source: salt://foo.conf
    - template: jinja
    - defaults: {{ mydict | json }}
```

Unicode/Python 3 Compatibility Improvements

This release fixes a number of nagging issues with Unicode strings in Salt under Python 2 (ex. `'ascii' codec can't decode byte 0xd0`). For best results, use a UTF-8 locale (such as by setting the `LANG` environment variable to one which supports UTF-8. For example `en_US.UTF-8`, `de_DE.UTF-8`, `ru_RU.UTF-8`, `C.UTF-8`).

Additionally, a number of Python 3 compatibility fixes have been made, many of them having to do with file I/O and str/bytes mismatches.

We continue to work toward improving both Unicode and Python 3 compatibility and welcome any feedback.

Lots of Docker Improvements

Much Improved Support for Docker Networking

The *docker_network.present* state has undergone a full rewrite, which includes the following improvements:

Full API Support for Network Management

The improvements made to input handling in the *docker_container.running* state for 2017.7.0 have now been expanded to *docker_network.present*. This brings with it full support for all tunable configuration arguments.

Custom Subnets

Custom subnets can now be configured. Both IPv4 and mixed IPv4/IPv6 networks are supported. See *here* for more information.

Network Configuration in `docker_container.running` States

A long-requested feature has finally been added! It is now possible to configure static IPv4/IPv6 addresses, as well as links and labels. See *here* for more information.

Note: While the `containers` argument to *`docker_network.present`* will continue to be supported, it will no longer be the recommended way of ensuring that a container is attached to a network.

Improved Handling of Images from Custom Registries

Rather than attempting to parse the tag from the passed image name, Salt will now resolve that tag down to an image ID and use that ID instead.

Important: Due to this change, there are some backward-incompatible changes to image management. See below for a full list of these changes.

Backward-incompatible Changes to Docker Image Management

Passing image names to the following functions must now be done using separate `repository` and `tag` arguments:

- *`docker.build`*
- *`docker.commit`*
- *`docker.import`*
- *`docker.load`*
- *`docker.tag`*
- *`docker.sls_build`*

Additionally, the `tag` argument must now be explicitly passed to the *`docker_image.present`* state, unless the image is being pulled from a docker registry.

State and Execution Module Support for `docker run` Functionality

The *`docker_container.running`* state is good for containers which run services, but it is not as useful for cases in which the container only needs to run once. The `start` argument to *`docker_container.running`* can be set to `False` to prevent the container from being started again on a subsequent run, but for many use cases this is not sufficient. Therefore, the *`docker.run_container`* remote-execution function was added. When used on the Salt CLI, it will return information about the container, such as its name, ID, exit code, and any output it produces.

State support has also been added via the *docker_container.run* state. This state is modeled after the *cmd.run* state, and includes arguments like `onlyif`, `unless`, and `creates` to control whether or not the container is run.

Full API Support for `docker.logs`

This function now supports all of the functions that its Docker API counterpart does, allowing you to do things like include timestamps, and also suppress stdout/stderr, etc. in the return.

start Argument Added to `docker.create` Function

This removes the need to run *docker.start* separately when creating containers on the Salt CLI.

```
salt myminion docker.create image=foo/bar:baz command=/path/to/command start=True
```

Use SaltSSH Minions like regular Master-Minions

The Master process can now also call SSH minions as if they were connected to the master using ZeroMQ. By setting `enable_ssh_minions: True` in the master config file, the master will create a Salt SSH client process which connects to the minion and returns the output for the `salt` CLI to use like a regular minion. This can be used anywhere the LocalClient is used.

Exceptions Raised for Authentication/Authorization Errors

When sending `publish` commands via `master.py` and `masterapi.py` and an authorization or authentication problem is encountered, Salt will now raise the appropriate exceptions instead of returning an empty string: `''`.

The reasoning behind this change is to make it easier to debug various scenarios surrounding authentication and authorization issues more effectively.

Comparison Operators in Package Installation

Salt now supports using comparison operators (e.g. `>=1.2.3`) when installing packages on minions which use *yum/dnf* or *apt*. This is supported both in the *pkg.installed* state and in the `pkg.install` remote execution function.

Master Tops Changes

When both *Master Tops* and a *Top File* produce SLS matches for a given minion, the matches were being merged in an unpredictable manner which did not preserve ordering. This has been changed. The top file matches now execute in the expected order, followed by any master tops matches that are not matched via a top file.

To make master tops matches execute first, followed by top file matches, set the new *master_tops_first* minion config option to `True`.

Several Jinja Filters Renamed

The following Jinja filters (originally added in 2017.7.0) have been renamed due to the fact that they were inaccurately named when initially added. The original names will be supported until the 3000 release of Salt.

- `rand_str` renamed to *`random_hash`*
- `jinja_decode_dict` renamed to `jinja_encode_dict`
- `jinja_decode_list` renamed to `jinja_encode_list`

Return Codes for Runner/Wheel Functions

When using *orchestration*, runner and wheel functions used to report a `True` result if the function ran to completion without raising an exception. It is now possible to set a return code in the `__context__` dictionary, allowing runner and wheel functions to report that they failed. Here's some example pseudocode:

```
def myrunner():
    ...
    do stuff
    ...
    if some_error_condition:
        __context__['retcode'] = 1
    return result
```

Variable Update Intervals for Fileserver Backends

Prior to this release, fileservers would be updated as part of a dedicated "maintenance" process, in which various routine maintenance tasks were performed. This tied the update interval to the *`loop_interval`* config option, and also forced all fileservers to update at the same interval.

2018.3.0 adds the following configuration options for the various fileserver backends:

- *`roots_update_interval`*
- *`azurefs_update_interval`*
- *`gitfs_update_interval`*
- *`hgfs_update_interval`*
- *`minionfs_update_interval`*
- *`s3fs_update_interval`*
- *`svnfs_update_interval`*

These allow for update intervals to be set for each individual backend. The default value for each of these is 60 seconds.

In addition, for *GitFS* it is also possible to apply intervals to individual remotes. See *here* for examples.

Note: git_pillar does not yet support variable update intervals, this is targeted for the next feature release (2019.2.0).

LDAP via External Authentication Changes

In this release of Salt, if LDAP Bind Credentials are supplied, then these credentials will be used for all LDAP access except the first authentication when a job is submitted. The first authentication will use the user's credentials as passed on the CLI. This behavior is to accommodate certain two-factor authentication schemes where the authentication token can only be used once.

In previous releases the bind credentials would only be used to determine the LDAP user's existence and group membership. The user's LDAP credentials were used from then on.

Stormpath External Authentication Removed

Per Stormpath's announcement, their API will be shutting down on 8/17/2017 at noon PST so the Stormpath external authentication module has been removed.

New (Proxy) Minion Configuration Options

To be able to connect the Minion to the Master using a certain source IP address or port, the following options have been added:

- *`source_interface_name`*
- *`source_address`*
- *`source_ret_port`*
- *`source_publish_port`*

`environment` config option renamed to `saltenv`

The *`environment`* config option predates referring to a salt fileserver environment as a **saltenv**. To pin a minion to a single environment for running states, one would use *`environment`*, but overriding that environment would be done with the `saltenv` argument. For consistency, *`environment`* is now simply referred to as *`saltenv`*. There are no plans to deprecate or remove *`environment`*, if used it will log a warning and its value will be used as *`saltenv`*.

`lock_saltenv` config option added

If set to `True`, this option will prevent a minion from allowing the `saltenv` argument to override the value set in *`saltenv`* when running states.

Failed Minions for State/Function Orchestration Jobs Added to Changes Dictionary

For orchestration jobs which run states (or run remote execution functions and also use a *fail function* to indicate success or failure), minions which have `False` results were previously included as a formatted string in the comment field of the return for that orchestration job. This made the failed returns difficult to *parse programatically*. The failed returns in these cases are now included in the changes dictionary, making for much easier parsing.

Grains

- `fc_wwn` - Show all fibre channel world wide port names for a host, must be enabled with *fibre_channel_grains*
- `iscsi_iqn` - Show the iSCSI IQN name for a host
- `swap_total` - Show the configured swap_total for Linux, *BSD, OS X and Solaris/SunOS
- `virtual`:
  - identifies reports KVM and VMM hypervisors when running an OpenBSD guest
  - for detecting Solaris Logical Domains (LDOMs) running on T-Series SPARC hardware. The `virtual_subtype` grain is populated as a list of domain roles.

Salt Minion Auto-discovery

Using auto-discovery, the Salt Minion now no longer needs to be configured against a specific DNS name or IP address of a Master.

For this feature Salt Master now requires port 4520 for UDP broadcast packets to be opened and the Salt Minion be able to send UDP packets to the same port.

Configuration

By default, automatic discovery is disabled.

Warning: Due to the current limitations that will be changing in a future release, before you turn on auto-discovery, make sure your network is secured and trusted.

Auto-discovery is configured on Master and Minion. Both of them are configured via the `discovery` option as follows:

Master configuration

To use the default configuration, which accepts any minion, simply set `discovery` to True:

```
discovery: true
```

A sub-option called *mapping* allows auto-discovery to help find the proper Master. The mapping contains an arbitrary set of key/value pairs, which the Minion configuration can target. By default, no mappings are set.

Example:

```
discovery:
  mapping:
    description: SES 5.0
    node: 1
```

It is also possible to change the port used from the default of `4520`, by setting a `port` option under the Master's `discovery` configuration:

```
discovery:
  port: 4567
```

Note: When using a port number other than the default, the Minion's `discovery` configuration must *also* have a port specified, otherwise the Minion will still attempt to contact the Master on port `4520`.

Minion configuration

In addition to the `mapping` and `port` options, the following additional options are available to Minions:

- `attempts` - This option specifies how many broadcast requests should be sent to the network, waiting for any Master response. Each attempt takes a couple of seconds, so raising this value may result in a slower Minion startup. Note that, on a properly-configured network, autodiscovery should succeed on the first attempt. By default, this value is set to `3`.
- `match` - This option can be set to either `all` or `any`, and it determines how the values configured in `mapping` are matched. If set to `all`, then all of the key/value pairs in the Minion's `mapping` must match a given Master. If set to `any` (the default), then any match to a key/value mapping will constitute a match.
- `pause` - The interval in seconds between attempts (default: 5).
- `fibre_channel_grains` - Enables the `fc_wwn` grain. (Default: False)
- `iscsi_grains` - Enables the `iscsi_iqn` grain. (Default: False)

Connection to a type instead of DNS

By now each Minion was connecting to a Master by DNS or IP address. From now on it is possible also to connect to a _type_ of a Master. For example, in a network there are three different Masters, each corresponds for a particular niche or environment or specific role etc. The Minion is supposed to connect only to one of those Masters that is described appropriately.

To achieve such an effect, each `/etc/salt/master` configuration should have a `discovery` option, which should have a `mapping` element with arbitrary key/value pairs. The same configuration should be on the Minion, so then when mapping matches, Minion recognises Master as its connection target.

Example for Master configuration (`/etc/salt/master`):

```
discovery:
  mapping:
    description: SES 5.0
    node: 1
```

The example above describes a system that is running a particular product, where `description` is an arbitrary key and `SES 5.0` is just a string. In order to match exactly this Master, the following configuration at Minion should be present:

```
discovery:
  match: all  # Can be "all" or "any"
  mapping:
    description: SES 5.0
    node: 1
```

Notice `match` criteria is set to `all`. This would mean that from all found Masters select only that, which `description` is set to `SES 5.0` _and_ `node` is set to `1`. All other Masters will be ignored.

Limitations

This feature has a couple of _temporary_ limitations that are subject to change in the future:

- Only one Master on the network is supported. Currently the Minion cannot select which Master out of few the same to choose. This will change to choosing the Master that is least loaded.
- Minions will accept _any_ master that matches connection criteria without any particular security applied (priv/pub key check, signature, fingerprint etc). That implies that administrator is expected to know his network and make sure it is clean.

New Modules

- *`salt.modules.purefa`*

New NaCl Renderer

A new renderer has been added for encrypted data.

New support for Cisco UCS Chassis

The salt proxy minion now allows for control of Cisco USC chassis. See the `cimc` modules for details.

New support for Cassandra v3

The `cassandra_cql` module now supports Cassandra v3 which has changed its internal schema to define keyspaces and columns.

New salt-ssh roster

A new roster has been added that allows users to pull in a list of hosts for salt-ssh targeting from a `~/.ssh` configuration. For full details, please see the `sshconfig` roster.

New GitFS Features

Two new features which affect how GitFS maps branches/tags to fileserver environments (i.e. `saltenvs`) have been added:

1. It is now possible to completely turn off Salt's default mapping logic (aside from the mapping of the `base` saltenv). This can be triggered using the new *`gitfs_disable_saltenv_mapping`* config option.

   Note: When this is disabled, only the `base` saltenv and any configured using *per-saltenv configuration parameters* will be available.

2. The types of refs which Salt will use as saltenvs can now be controlled. In previous releases, branches and tags were both mapped as environments, and individual commit SHAs could be specified as saltenvs in states (and when caching files using *`cp.cache_file`*). Using the new *`gitfs_ref_types`* config option, the types of refs which are used as saltenvs can be restricted. This makes it possible to ignore all tags and use branches only, and also to keep SHAs from being made available as saltenvs.

Additional output modes

The `state_output` parameter now supports `full_id`, `changes_id` and `terse_id`. Just like `mixed_id`, these use the state ID as name in the highstate output. For more information on these output modes, see the docs for the *`Highstate Outputter`*.

Windows

Python Version

Python 2 Windows API was design when Windows did not support Unicode. Windows now supports Unicode however to keep backwards compatibility Python 2 Windows API has not been changed. Python 3 Windows API supports Unicode. Salt Python 3 installer is the recommend choice for users who need characters other than Non-ASCII (7bit) characters.

`pkg` Execution module changes

Significant changes have been made to the *`win_pkg`* execution module. Users should test this release against their existing package sls definition files. These changes are also in 2016.11.9 & 2017.7.3.

- `pkg.list_available` no longer defaults to refreshing the winrepo meta database.
- `pkg.install` without a `version` parameter no longer upgrades software if the software is already installed. Use `pkg.install version=latest` or in a state use `pkg.latest` to get the old behavior.
- `pkg.list_pkgs` now returns multiple versions if software installed more than once.
- `pkg.list_pkgs` now returns 'Not Found' when the version is not found instead of '(value not set)' which matches the contents of the sls definitions.
- `pkg.remove()` will wait up to 3 seconds (normally about a second) to detect changes in the registry after removing software, improving reporting of version changes.
- `pkg.remove()` can remove `latest` software, if `latest` is defined in sls definition.
- Documentation was update for the execution module to match the style in new versions, some corrections as well.
- All install/remove commands are prefix with cmd.exe shell and cmdmod is called with a command line string instead of a list. Some sls files in saltstack/salt-winrepo-ng expected the commands to be prefixed with cmd.exe (i.e. the use of &).
- Some execution module functions results, now behavour more like their Unix/Linux versions.

Installer

Changes to config handling

Behavior with existing configuration has changed. With previous windows installers the existing config was used and the master and minion id could be modified via the installer. It was problematic in that it didn't account for configuration that may be defined in the `minion.d` directory. This change gives you the option via a drop-down list to use one of the following:

- Default Config: Use the config that comes with the installer
- Existing Config: Use the current config without changes

- Custom Config: Select a custom config using the file picker

The existing config option will only be available if the installer detects an existing config. If there is an existing config, and you choose `Default` or `Custom`, the existing config will be deleted, including the `minion.d` directory, and replaced by your selection.

The `Default Config` and `Custom Config` options will allow you to modify the Master and the Minion ID. `Existing Config` will leave the existing configuration unchanged.

These settings can be defined on the command line using the following switches:

- `/default-config`
- `/custom-config=C:\Path\To\Custom\Config\minion`

If neither option is passed and there is an existing config, the default is to use the existing config. If there is no existing config (new install) the default config will be used.

Multi-master configuration

The installer now has the ability to apply a multi-master configuration either from the GUI or the command line. The `master` field in the GUI can accept either a single master or a comma-separated list of masters. The command-line switch (`/master=`) can accept the same.

Command-line help

The Windows installer will now display command-line help when a help switch (`/?`) is passed.

New utils module `salt.utils.pkg.win`

A new utils module has been added, which gathers information about windows installed software. This is currently not used by any salt execution module or state at this time. Users are encouraged to run this and report any issues. Running the command with the `detail` option will be useful for anyone developing windows package definitions. With salt installed in the default location the following command will print the help message.

```
chcp 65001
c:\salt\bin\python.exe c:\salt\bin\lib\site-packages\salt\utils\pkg\win.py
c:\salt\bin\python.exe c:\salt\bin\lib\site-packages\salt\utils\pkg\win.py detail␣

```

Salt Cloud Features

OpenStack Revamp

The OpenStack Driver has been rewritten mostly from scratch. Salt is now using the *shade driver <https://docs.openstack.org/shade/latest/>*.

With this, the `nova` driver is being deprecated.

`openstack driver`

There have also been several new modules and states added for managing OpenStack setups using shade as well.

`keystone` `keystone role grant` `keystone group` `keystone role` `keystone service` `keystone user` `keystone domain` `keystone project` `keystone endpoint` `glance`

glance_image neutron neutron subnet neutron secgroup neutron secgroup rule neutron network

Pre-Flight Commands

Support has been added for specified "preflight commands" to run on a VM before the deploy script is run. These must be defined as a list in a cloud configuration file. For example:

```
my-cloud-profile:
  provider: linode-config
  image: Ubuntu 16.04 LTS
  size: Linode 2048
  preflight_cmds:
    - whoami
    - echo 'hello world!'
```

These commands will run in sequence **before** the bootstrap script is executed.

New salt-cloud Grains

When salt-cloud creates a new minion, it will now add grain information to the minion configuration file, identifying the resources originally used to create it.

The generated grain information will appear similar to:

```
grains:
  salt-cloud:
    driver: ec2
    provider: my_ec2:ec2
    profile: ec2-web
```

The generation of salt-cloud grains can be suppressed by the option `enable_cloud_grains: 'False'` in the cloud configuration file.

Upgraded Saltify Driver

The salt-cloud Saltify driver is used to provision machines which are not controlled by a dedicated cloud supervisor (such as typical hardware machines) by pushing a salt-bootstrap command to them and accepting them on the salt master. Creation of a node has been its only function and no other salt-cloud commands were implemented.

With this upgrade, it can use the salt-api to provide advanced control, such as rebooting a machine, querying it along with conventional cloud minions, and, ultimately, disconnecting it from its master.

After disconnection from ("destroying" on) one master, a machine can be re-purposed by connecting to ("creating" on) a subsequent master.

New Vagrant Driver

The salt-cloud Vagrant driver brings virtual machines running in a limited environment, such as a programmer's workstation, under salt-cloud control. This can be useful for experimentation, instruction, or testing salt configurations.

Using salt-api on the master, and a salt-minion running on the host computer, the Vagrant driver can create (`vagrant up`), restart (`vagrant reload`), and destroy (`vagrant destroy`) VMs, as controlled by salt-cloud profiles which designate a `Vagrantfile` on the host machine.

The master can be a very limited machine, such as a Raspberry Pi, or a small VagrantBox VM.

Python PyWinRM Module

Versions of `pywinrm>=0.2.1` are finally able to disable validation of self signed certificates. *Here* for more information.

DigitalOcean

The DigitalOcean driver has been renamed to conform to the company name. The new driver name is `digitalocean`. The old name `digital_ocean` and a short one `do` will still be supported through virtual aliases, this is mostly cosmetic.

Azure Cloud

The azure sdk used for the `azurearm` cloud driver now depends on `azure-cli>=2.0.12`

New `saltclass` pillar/master_tops modules

This module clones the behaviour of reclass (http://reclass.pantsfullofunix.net/), without the need of an external app, and add several features to improve flexibility. Saltclass lets you define your nodes from simple `yaml` files (`.yml`) through hierarchical class inheritance with the possibility to override pillars down the tree.

Features

- Define your nodes through hierarchical class inheritance
- Reuse your reclass data with minimal modifications
  - applications => states
  - parameters => pillars
- Use Jinja templating in your yaml definitions
- Access to the following Salt objects in Jinja
  - `__opts__`
  - `__salt__`
  - `__grains__`
  - `__pillars__`
  - `minion_id`
- Chose how to merge or override your lists using ^ character (see examples)
- Expand variables ${} with possibility to escape them if needed ${} (see examples)
- Ignores missing node/class and will simply return empty without breaking the pillar module completely - will be logged

An example subset of data is available here: http://git.mauras.ch/salt/saltclass/src/master/examples

Terms usable in yaml files	Description
classes	A list of classes that will be processed in order
states	A list of states that will be returned by master_tops function
pillars	A yaml dictionary that will be returned by the ext_pillar function
environment	Node saltenv that will be used by master_tops

A class consists of:

- zero or more parent classes
- zero or more states
- any number of pillars

A child class can override pillars from a parent class. A node definition is a class in itself with an added `environment` parameter for `saltenv` definition.

Class Names

Class names mimic salt way of defining states and pillar files. This means that `default.users` class name will correspond to one of these:

- `<saltclass_path>/classes/default/users.yml`
- `<saltclass_path>/classes/default/users/init.yml`

Saltclass Tree

A saltclass tree would look like this:

```
<saltclass_path>

│   │   ├── borgbackup.yml
│   │   └── ssh
│   │       └── server.yml

```

Known limitation

Currently you can't have both a variable and an escaped variable in the same string as the escaped one will not be correctly rendered - '${xx}' will stay as is instead of being rendered as '${xx}'

Lists of comments in state returns

State functions can now return a list of strings for the `comment` field, as opposed to only a single string. This is meant to ease writing states with multiple or multi-part comments.

Beacon configuration changes

In order to remain consistent and to align with other Salt components such as states, support for configuring beacons using dictionary based configuration has been deprecated in favor of list based configuration. All beacons have a validation function which will check the configuration for the correct format and only load if the validation passes.

avahi_announce

Old behavior:

```

New requisites available in state compiler

require_any

The use of `require_any` demands that one of the required states executes before the dependent state. The state containing the `require_any` requisite is defined as the dependent state. The states specified in the `require_any` statement are defined as the required states. If at least one of the required state's execution succeeds, the dependent state will then execute. If all of the executions by the required states fail, the dependent state will not execute.

watch_any

The state containing the `watch_any` requisite is defined as the watching state. The states specified in the `watch_any` statement are defined as the watched states. When the watched states execute, they will return a dictionary containing a key named "changes".

If the "result" of any of the watched states is `True`, the watching state *will execute normally*, and if all of them are `False`, the watching state will never run. This part of `watch` mirrors the functionality of the `require` requisite.

If the "result" of any of the watched states is `True` *and* the "changes" key contains a populated dictionary (changes occurred in the watched state), then the `watch` requisite can add additional behavior. This additional behavior is defined by the `mod_watch` function within the watching state module. If the `mod_watch` function exists in the watching state module, it will be called *in addition to* the normal watching state. The return data from the `mod_watch` function is what will be returned to the master in this case; the return data from the main watching function is discarded.

If the "changes" key contains an empty dictionary, the `watch` requisite acts exactly like the `require` requisite (the watching state will execute if "result" is `True`, and fail if "result" is `False` in the watched state).

onchanges_any

The `onchanges_any` requisite makes a state only apply one of the required states generates changes, and if one of the watched state's "result" is `True`. This can be a useful way to execute a post hook after changing aspects of a system.

onfail_any

The `onfail_any` requisite allows for reactions to happen strictly as a response to the failure of at least one other state. This can be used in a number of ways, such as executing a second attempt to set up a service or begin to execute a separate thread of states because of a failure.

The `onfail_any` requisite is applied in the same way as `require_any` and `watch_any`.

Basic Slots support in state compiler

Slots extend the state syntax and allows you to do things right before the state function is executed. So you can make a decision in the last moment right before a state is executed.

Slot syntax looks close to the simple python function call. Here is a simple example:

```
copy-some-file:
  file.copy:
    - name: __slot__:salt:test.echo(text=/tmp/some_file)
    - source: __slot__:salt:test.echo(/etc/hosts)
```

Read more *here*.

Cryptographic layer changes

M2Crypto is coming back. We are making the crypto backend modular but in this release M2Crypto is enabled if it's importable by Python. If not Cryptodome or PyCrypto is used as it was in the previous releases. M2Crypto is used in the same way as PyCrypto so there would be no compatibility issues, different nodes could use different backends.

NaCL Module and Runner changes

In addition to argument changes in both the NaCL module and runner for future removal in the 3000 release, the default "box_type" has changed from `secretbox` to `sealedbox`. SecretBox is data encrypted using private key `sk` and Sealedbox is encrypted using public key `pk`.

`utils` functions reorganized into separate modules

The Salt utility functions from `salt.utils` (typically used by those developing extension modules for Salt) have been moved into different modules, grouped logically based on their functionality. The old function names will continue to work until the `3000` release of Salt (due around Q1 2019).

The renamed functions are:

- `salt.utils.appendproctitle`: use `salt.utils.process.appendproctitle` instead.
- `salt.utils.daemonize`: use `salt.utils.process.daemonize` instead.
- `salt.utils.daemonize_if`: use `salt.utils.process.daemonize_if` instead.
- `salt.utils.reinit_crypto`: use `salt.utils.crypt.reinit_crypto` instead.
- `salt.utils.pem_finger`: use `salt.utils.crypt.pem_finger` instead.
- `salt.utils.to_bytes`: use `salt.utils.stringutils.to_bytes` instead.
- `salt.utils.to_str`: use `salt.utils.stringutils.to_str` instead.
- `salt.utils.to_unicode`: use `salt.utils.stringutils.to_unicode` instead.
- `salt.utils.str_to_num`: use `salt.utils.stringutils.to_num` instead.
- `salt.utils.is_quoted`: use `salt.utils.stringutils.is_quoted` instead.
- `salt.utils.dequote`: use `salt.utils.stringutils.dequote` instead.
- `salt.utils.is_hex`: use `salt.utils.stringutils.is_hex` instead.

- `salt.utils.is_bin_str`: use `salt.utils.stringutils.is_bin_str` instead.
- `salt.utils.rand_string`: use `salt.utils.stringutils.random` instead.
- `salt.utils.contains_whitespace`: use `salt.utils.stringutils.contains_whitespace` instead.
- `salt.utils.build_whitespace_split_regex`: use `salt.utils.stringutils.build_whitespace_split_regex` instead.
- `salt.utils.expr_match`: use `salt.utils.stringutils.expr_match` instead.
- `salt.utils.check_whitelist_blacklist`: use `salt.utils.stringutils.check_whitelist_blacklist` instead.
- `salt.utils.check_include_exclude`: use `salt.utils.stringutils.check_include_exclude` instead.
- `salt.utils.print_cli`: use `salt.utils.stringutils.print_cli` instead.
- `salt.utils.clean_kwargs`: use `salt.utils.args.clean_kwargs` instead.
- `salt.utils.invalid_kwargs`: use `salt.utils.args.invalid_kwargs` instead.
- `salt.utils.shlex_split`: use `salt.utils.args.shlex_split` instead.
- `salt.utils.arg_lookup`: use `salt.utils.args.arg_lookup` instead.
- `salt.utils.argspec_report`: use `salt.utils.args.argspec_report` instead.
- `salt.utils.split_input`: use `salt.utils.args.split_input` instead.
- `salt.utils.test_mode`: use `salt.utils.args.test_mode` instead.
- `salt.utils.format_call`: use `salt.utils.args.format_call` instead.
- `salt.utils.which`: use `salt.utils.path.which` instead.
- `salt.utils.which_bin`: use `salt.utils.path.which_bin` instead.
- `salt.utils.path_join`: use `salt.utils.path.join` instead.
- `salt.utils.check_or_die`: use `salt.utils.path.check_or_die` instead.
- `salt.utils.sanitize_win_path_string`: use `salt.utils.path.sanitize_win_path` instead.
- `salt.utils.rand_str`: use `salt.utils.hashutils.random_hash` instead.
- `salt.utils.get_hash`: use `salt.utils.hashutils.get_hash` instead.
- `salt.utils.is_windows`: use `salt.utils.platform.is_windows` instead.
- `salt.utils.is_proxy`: use `salt.utils.platform.is_proxy` instead.
- `salt.utils.is_linux`: use `salt.utils.platform.is_linux` instead.
- `salt.utils.is_darwin`: use `salt.utils.platform.is_darwin` instead.
- `salt.utils.is_sunos`: use `salt.utils.platform.is_sunos` instead.
- `salt.utils.is_smartos`: use `salt.utils.platform.is_smartos` instead.
- `salt.utils.is_smartos_globalzone`: use `salt.utils.platform.is_smartos_globalzone` instead.
- `salt.utils.is_smartos_zone`: use `salt.utils.platform.is_smartos_zone` instead.
- `salt.utils.is_freebsd`: use `salt.utils.platform.is_freebsd` instead.

- `salt.utils.is_netbsd`: use `salt.utils.platform.is_netbsd` instead.
- `salt.utils.is_openbsd`: use `salt.utils.platform.is_openbsd` instead.
- `salt.utils.is_aix`: use `salt.utils.platform.is_aix` instead.
- `salt.utils.safe_rm`: use `salt.utils.files.safe_rm` instead.
- `salt.utils.is_empty`: use `salt.utils.files.is_empty` instead.
- `salt.utils.fopen`: use `salt.utils.files.fopen` instead.
- `salt.utils.flopen`: use `salt.utils.files.flopen` instead.
- `salt.utils.fpopen`: use `salt.utils.files.fpopen` instead.
- `salt.utils.rm_rf`: use `salt.utils.files.rm_rf` instead.
- `salt.utils.mkstemp`: use `salt.utils.files.mkstemp` instead.
- `salt.utils.istextfile`: use `salt.utils.files.is_text_file` instead.
- `salt.utils.is_bin_file`: use `salt.utils.files.is_binary` instead.
- `salt.utils.list_files`: use `salt.utils.files.list_files` instead.
- `salt.utils.safe_walk`: use `salt.utils.files.safe_walk` instead.
- `salt.utils.st_mode_to_octal`: use `salt.utils.files.st_mode_to_octal` instead.
- `salt.utils.normalize_mode`: use `salt.utils.files.normalize_mode` instead.
- `salt.utils.human_size_to_bytes`: use `salt.utils.files.human_size_to_bytes` instead.
- `salt.utils.backup_minion`: use `salt.utils.files.backup_minion` instead.
- `salt.utils.str_version_to_evr`: use `salt.utils.pkg.rpm.version_to_evr` instead.
- `salt.utils.parse_docstring`: use `salt.utils.doc.parse_docstring` instead.
- `salt.utils.compare_versions`: use `salt.utils.versions.compare` instead.
- `salt.utils.version_cmp`: use `salt.utils.versions.version_cmp` instead.
- `salt.utils.warn_until`: use `salt.utils.versions.warn_until` instead.
- `salt.utils.kwargs_warn_until`: use `salt.utils.versions.kwargs_warn_until` instead.
- `salt.utils.get_color_theme`: use `salt.utils.color.get_color_theme` instead.
- `salt.utils.get_colors`: use `salt.utils.color.get_colors` instead.
- `salt.utils.gen_state_tag`: use `salt.utils.state.gen_tag` instead.
- `salt.utils.search_onfail_requisites`: use `salt.utils.state.search_onfail_requisites` instead.
- `salt.utils.check_state_result`: use `salt.utils.state.check_result` instead.
- `salt.utils.get_user`: use `salt.utils.user.get_user` instead.
- `salt.utils.get_uid`: use `salt.utils.user.get_uid` instead.

- The `requests_lib` configuration option has been removed. Please use `backend` instead.

Profitbricks Cloud Updated Dependency

The minimum version of the `profitbrick` python package for the `profitbricks` cloud driver has changed from 3.0.0 to 3.1.0.

Execution Module Deprecations

- The `blockdev` execution module has been removed. Its functions were merged with the *`disk`* module.
- The *`lxc`* execution module has been changed as follows:
  - The `dnsservers` option to *`lxc.cloud_init_interface`* no longer defaults to `4.4.4.4` and `8.8.8.8`.
  - The `dns_via_dhcp` option to *`lxc.cloud_init_interface`* now defaults to `True` instead of `False`.
- The *`win_psget`* module has been changed as follows:
  - The `psget.psversion` function was removed. Please use *`cmd.shell_info`* instead.
- The *`win_service`* module (which provides the `service` module on Windows platforms) has been changed as follows:
  - The `config` function was removed. Please use *`service.modify`* instead.
  - The following arguments to the *`service.create`* function have been renamed:
    - `binpath` has been renamed to `bin_path`
    - `depend` has been renamed to `dependencies`
    - `DisplayName` has been renamed to `display_name`
    - `error` has been renamed to `error_control`
    - `group` has been renamed to `load_order_group`

    - `obj` has been renamed to `account_name`
    - `password` has been renamed to `account_password`
    - `start` has been renamed to `start_type`
    - `type` has been renamed to `service_type`
- The *nacl* module has been changed as follows:
  - The following arguments have been renamed in the *nacl.keygen*, *nacl.enc*, and *nacl.dec*:
    - `key_file` has been renamed to `sk_file`
    - `key` has been renamed to `sk`

Runner Deprecations

- The *manage* runner has been changed as follows:
  - `root_user` argument was removed from the *manage.bootstrap* function. Please use `salt-ssh` roster entries for the host instead.
- The *nacl* runner has been changed as follows:
  - The following arguments have been renamed in the *nacl.keygen*, *nacl.enc*, and *nacl.dec*:
    - `key_file` has been renamed to `sk_file`
    - `key` has been renamed to `sk`

State Deprecations

- In the `archive` state, the `tar_options` and `zip_options` options were removed. Please use `options` instead.
- The `cmd` state had the following changes:
  - The `user` and `group` options were removed from the following functions (please use `runas` instead):
    - *cmd.run*
    - *cmd.script*
    - `cmd.wait`
    - `cmd.wait_script`
- In the *file* states, the `show_diff` option was removed in all states where it was previously supported. Please use `show_changes` instead.

Grain Deprecations

- For `smartos`, some grains have been deprecated. These grains will be removed in 3000:
  - The `hypervisor_uuid` grain has been replaced with `mdata:sdc:server_uuid`
  - The `datacenter` grain has been replaced with `mdata:sdc:datacenter_name`

Pillar Deprecations

The legacy configuration for `git_pillar` has been removed. Please use the new configuration for `git_pillar` which was added in 2015.8.0, which is documented *here*.

Utils Deprecations

- In `salt.utils.cloud`, the `fire_event` function now requires a `sock_dir` argument. It was previously optional.

Other Miscellaneous Deprecations

- In `version.py`, the `rc_info` function was removed. Please use `pre_info` instead.
- Warnings for moving away from the `env` option were removed. `saltenv` should be used instead. The removal of these warnings does not have a behavior change. Only the warning text was removed.

Minion Blackout

During a blackout, minions will not execute any remote execution commands, except for *`saltutil.refresh_pillar`*. Previously, support was added so that blackouts are enabled using a special pillar key, `minion_blackout` set to `True` and an optional pillar key `minion_blackout_whitelist` to specify additional functions that are permitted during blackout. This release adds support for using this feature in the grains as well, by using special grains keys `minion_blackout` and `minion_blackout_whitelist`.

Sentry Log Handler

Configuring sentry raven python client via `project`, `servers`, `public_key and ``secret_key` is deprecated and won't work with sentry clients > 3.0. Instead, the `dsn` config param must be used.

RAET transport

We haven't been doing development on RAET for quite some time and decided that 2018.3.0 is the time to announce the deprecation. RAET support will be removed in 3000. Please consider to move to `zeromq` or `tcp` transport instead of `raet`.

28.2.12 Salt 2018.3.1 Release Notes

Version 2018.3.1 is a bugfix release for *2018.3.0*.

Warning: If you are using Jinja to dump lists or dictionaries in your SLS files, this will now cause errors in Python 2 since Jinja does not produce YAML-compatible output when strings in the data structures contain unicode types. The dictionary must be passed through a Jinja filter to produce YAML-compatible strings.

The below is an example of invalid SLS:

```
/etc/foo.conf:
  file.mangaged:
    - source: salt://foo.conf
    - template: jinja
    - defaults: {{ mydict }}
```

To make it valid, use either one of Salt's own `json` or `yaml` filters:

```
/etc/foo.conf:
  file.mangaged:
    - source: salt://foo.conf
    - template: jinja
    - defaults: {{ mydict | json }}
```

Tornado 5.0 Support for Python 2 Only

Tornado 5.0 moves to using asyncio for all python3 versions. Because of this and changes in asyncio between python 3.4 and 3.5 to only be able to use one ioloop, which requires some rearchitecting, support for tornado 5.0 and python3 versions of salt has been delayed to a later release.

For now, to use tornado 5.0, the python 2 version of salt must be used.

Changes to Slack Engine pillars

When using `groups_pillar_name` for the slack engine, the engine should be used as part of a salt-minion process running on the master. This will allow the minion to have pillars assigned to it, and will still allow the engine to create a LocalClient connection to the master ipc sockets to control environments.

Changes to Automatically Updating the Roster File

In `2018.3.0` salt-ssh was configured to automatically update the flat roster file if a minion was not found for salt-ssh. This was decided to be undesireable as a default. The `--skip-roster` flag has been removed and replaced with `--update-roster`, which will enable salt-ssh to add minions to the flat roster file. This behavior can also be enabled by setting `ssh_update_roster: True` in the master config file.

Changes to `file.blockreplace` State

The `append_newline` argument was added to this state. Additionally, to improve idempotence, if the string represented by `marker_end` is found in the middle of the line, the content preceding the marker will be removed when the block is replaced. This allows one to remove `append_newline: False` from the SLS and have the block properly replaced if the end of the content block is immediately followed by the `marker_end` (i.e. no newline before the marker).

Note: This will require changes to your SLS if your `marker_end` does not include the very beginning of the content you want to keep.

See the *`file.blockreplace`* state documentation for further information.

    - 6f183e1d80 Initial commmit for unit/engines/test_slack_engine
    - a2840fc230 Only include the rest of the cmdline if the cmd is an alias.

  - e846df7409 Fixing a bug when passing pillar values to aliases for the Slack engine. Cleaned up the formatting of the results, color codes don't translate well into Slack output. For any state runs, eg. highstate. apply, sls, we run the output through the highstate formater. For anything else run it though the yaml outputer. Running it though highstate causes errors when the output does match what the highstate output is expecting.

- **PR** #47219: (garethgreenaway) [2018.3] Fixing a backward compatibility issue with vault module & runner @ *2018-04-23 14:10:19 UTC*
  - 88557ea991 Merge pull request #47219 from garethgreenaway/vault_backward_compatibility
  - 1758081ffe When using the vault module on a 2018.3 minion against a 2017.7 master, the 2018.3 minion is expecting a verify element in the results from the Salt runner on the master. The runner in 2017.7 did not include a verify element, which results in an error. This change accounts for this by using the default in 2018.3 which is not to verify if not configured.

    - f038e3c452 Merge pull request #46571 from garethgreenaway/46552_onfail_and_require
      - 152c43c843 Accounting for a case when multiple onfails are used along with requires. Previously if you have multiple states using 'onfail' and two of those states using a 'require' against the first one state, the last two will run even if the 'onfail' isn't met because the 'require' is met because the first state returns true even though it didn't excute. This change adds an additional hidden variable that is used when checking requisities to determine if the state actually ran.

28.2.13 Salt 2018.3.2 Release Notes

Version 2018.3.2 is a bugfix release for *2018.3.0*.

The `2018.3.2` release contains only a small number of fixes, which are detailed below.

This release fixes two critical issues.

The first is Issue #48038, which is a critical bug that occurs in a multi-syndic setup where the same job is run multiple times on a minion.

The second issue is #48130. This bug appears in certain setups where the Master reports a Minion time-out, even though the job is still running on the Minion.

Both of these issues have been fixed with this release.

28.2.14 Salt 2018.3.3 Release Notes

Version 2018.3.3 is a security and bugfix release for *2018.3.0*.

Warning: If you are using Jinja to dump lists or dictionaries in your SLS files, this will now cause errors in Python 2 since Jinja does not produce YAML-compatible output when strings in the data structures contain unicode types. The dictionary must be passed through a Jinja filter to produce YAML-compatible strings.

The below is an example of invalid SLS:

```
/etc/foo.conf:
  file.mangaged:
    - source: salt://foo.conf
    - template: jinja
    - defaults: {{ mydict }}
```

To make it valid, use either one of Salt's own `json` or `yaml` filters. Another option would be to use Jinja's *tojson* filter.

```
/etc/foo.conf:
  file.mangaged:
    - source: salt://foo.conf
    - template: jinja
    - defaults: {{ mydict | tojson }}
```

Security Fix

CVE-2018-15751 Remote command execution and incorrect access control when using salt-api.

CVE-2018-15750 Directory traversal vulnerability when using salt-api. Allows an attacker to determine what files exist on a server when querying /run or /events.

Changes to win_timezone

Improves timezone detection by using the pytz module.

`timezone.get_offset` and `timezone.get_zonecode` now work properly.

Adds `timezone.list` to list supported timezones in either Windows or Unix format.

New Jinja Filter

The `tojson` filter (from Jinja 2.9 and later) has been ported to Salt, and will be used when this filter is not available. This allows older LTS releases such as CentOS 7 and Ubuntu 14.04 to use this filter.

You can use this filter any time you wish to dump a list or dictionary into an SLS file, to ensure that the result is able to be loaded by the YAML renderer. For example:

```
foo:
  bar.baz:
    - some_arg: {{ mydict | tojson }}
```

MacOSX escape characters with runas

You are now required to escape quotes when using the runas argument with the cmd module on macosx.

Example:

```
cmd.run 'echo '\''h=\"baz\"'\''' runas=macuser
```

      - 9b0f5dd212 Fixing identation, removing some unnecessary conditionals.
      - 727964ab55 One last cleanup.
      - 11cb86e6eb General cleanup in pkg state, reducing duplicate code. Fixing the requires_salt_modules decorator, sys.doc was returning too much information for the event to handle. This change specifically calls sys.doc with the module name.
      - 16fb6ae635 Make sure pkg.hold and pkg.unhold are available before running the test.
      - 998651102d Fixing a situation when a package is already installed via salt or manually and a state attempts to set that package to be held. Previously the holding/unholding logic was only being run against packages that were being installed. This change moves the holding

logic outside and runs it against all desired packages. Adding a new test to test holding logic.

28.2.15 Salt 2018.3.4 Release Notes

Version 2018.3.4 is a bugfix release for *2018.3.0*.

State Changes

- The `host.present` state can now remove the specified hostname from IPs not specified in the state. This can be done by setting the newly-added `clean` argument to `True`.

    - 6679242 Merge pull request #50590 from garethgreenaway/bp-50333
      - 1f5aa4b pkg.installed currently fails when sources is used along with hold: True. This was due to a change in #48426 that swapped out sending the pkgs variable for the desired variable instead. This caused problems with pkg.hold because desired and sources are always populated, and pkg.hold can only include one or the other. This change just includes desired in the call to pkg.hold since desired has the same value for sources.

  - 7bc9b3d Merge branch '2018.3' into 50311_pkg_installed_fails_sources_hold
  - 6e96728 pkg.installed currently fails when sources is used along with hold: True. This was due to a change in #48426 that swapped out sending the pkgs variable for the desired variable instead. This caused problems with pkg.hold because desired and sources are always populated, and pkg.hold can only include one or the other. This change just includes desired in the call to pkg.hold since desired has the same value for sources.

  - eedeacb Updating another reference to salt.utils.mac_utils to use __utils__
    - 6ef5ce4 Due to a previous PR the test_sdb_runner in sdb.test_vault was failing because of a exception that was being swallowed in the test run_run function. The cause was that when vault related functions were being run, if they were being run on the master then they were being forced to run through the _get_token_and_url_from_master() function, which is pull the id element out of the grains dictionary. When the call was taking place from a runner, the exception was popping up since there is no id when called from a runner. This fix checks to see if the id exists in the dictionary first, if it is there then _get_token_and_url_from_master() is called, otherwise _use_local_config is called.

28.2.16 Salt 2018.3.5 Release Notes

Version 2018.3.5 is a CVE-fix release for *2018.3.0*.

Security Fix

CVE-2019-17361

With the Salt NetAPI enabled in addition to having a SSH roster defined, unauthenticated access is possible when specifying the client as SSH. Additionally, when the raw_shell option is specified any arbitrary command may be run on the Salt master when specifying SSH options.

28.2.17 Salt 2017.7.0 Release Notes - Codename Nitrogen

28.2.18 Python 3

The 2017.7 Salt Release adds initial Python 3 support.

The default Python version of Salt will remain Python 2, although Python 3 packages will be supplied for users who want to help test this new feature.

28.2.19 Python 2.6 Deprecation

Salt will no longer support Python 2.6. We will provide python2.7 packages on our repo for RedHat and CentOS 6 to ensure users can still run Salt on these platforms.

As this will impact the installation of additional dependencies for salt modules please use pip packages if there is not a package available in a repository. You will need to install the python27-pip package to get access to the correct pip27 executable: `yum install python27-pip`

28.2.20 Known Issues

The following salt-cloud drivers have known issues running with Python 3. These drivers will not work with Python 3, and Python 2.7 should be used instead:

- Joyent
- When running under Python 3, users who require Unicode support should ensure that a locale is set on their machines. Users using the *C* locale are advised to switch to a UTF-aware locale to ensure proper functionality with Salt with Python 3.

Remember to update the Salt Master first

Salt's policy has always been that when upgrading, the minion should never be on a newer version than the master. Specifically with this update, because of changes in the fileclient, the 2017.7 minion requires a 2017.7 master.

Backwards compatibility is still maintained, so older minions can still be used.

More information can be found in the *Salt FAQ*

States Added for Management of systemd Unit Masking

The *`service.masked`* and *`service.umasked`* states have been added to allow Salt to manage masking of systemd units.

Additionally, the following functions in the `systemd` execution module have changed to accommodate the fact that indefinite and runtime masks can co-exist for the same unit:

- `service.masked` - The return from this function has changed from previous releases. Before, `False` would be returned if the unit was not masked, and the output of `systemctl is-enabled <unit name>` would be returned if the unit was masked. However, since indefinite and runtime masks can exist for the same unit at the same time, this function has been altered to accept a `runtime` argument. If `True`, the minion will be checked for a runtime mask assigned to the named unit. If `False`, then the minion will be checked for an indefinite mask. If one is found, `True` will be returned. If not, then `False` will be returned.

- `service.masked` - This function used to just run `systemctl is-enabled <unit name>` and based on the return from this function the corresponding mask type would be removed. However, if both runtime and indefinite masks are set for the same unit, then `systemctl is-enabled <unit name>` would show just the indefinite mask. The indefinite mask would be removed, but the runtime mask would remain. The function has been modified to accept a `runtime` argument, and will attempt to remove a runtime mask if that argument is set to `True`. If set to `False`, it will attempt to remove an indefinite mask.

These new `runtime` arguments default to `False`.

Pillar Encryption

Beginning in 2016.3.0 the CLI pillar data passed to several functions could conditionally be passed through a renderer to be decrypted. This functionality has now been extended to pillar SLS files as well. See *here* for detailed documentation on this feature.

Grains Changes

- The `osmajorrelease` grain has been changed from a string to an integer. State files, especially those using a templating language like Jinja, may need to be adjusted to account for this change.
- Add ability to specify disk backing mode in the VMWare salt cloud profile.

State Module Changes

- The *`service.running`* and *`service.dead`* states now support a `no_block` argument which, when set to `True` on systemd minions, will start/stop the service using the `--no-block` flag in the `systemctl` command. On non-systemd minions, a warning will be issued.
- The *`module.run`* state has dropped its previous syntax with `m_` prefix for reserved keywords. Additionally, it allows running several functions in a batch.

  Note: It is necessary to explicitly turn on the new behavior (see below)

```
# Before
run_something:
  module.run:
    - name: mymodule.something
    - m_name: 'some name'
    - kwargs: {
      first_arg: 'one',
      second_arg: 'two',
      do_stuff: 'True'
    }

# After
run_something:
  module.run:
    - mymodule.something:
      - name: some name
      - first_arg: one
      - second_arg: two
      - do_stuff: True
```

Since a lot of users are already using *module.run* states, this new behavior must currently be explicitly turned on, to allow users to take their time updating their SLS files. However, please keep in mind that the new syntax will take effect in the next feature release of Salt (Oxygen) and the old usage will no longer be supported at that time.

Another feature of the new *module.run* is that it allows calling many functions in a single batch, such as:

```
run_something:
  module.run:
    - mymodule.function_without_parameters:
    - mymodule.another_function:
      - myparam
      - my_other_param
```

In a rare case that you have a function that needs to be called several times but with the different parameters, an additional feature of "tagging" is to the rescue. In order to tag a function, use a colon delimiter. For example:

```
run_something:
  module.run:
    - mymodule.same_function:1:
    - mymodule.same_function:2:
      - myparam
      - my_other_param
    - mymodule.same_function:3:
      - foo: bar
```

The example above will run *mymodule.same_function* three times with the different parameters.

To enable the new behavior for *module.run*, add the following to the minion config file:

```
use_superseded:
  - module.run
```

- The default for the `fingerprint_hash_type` option used in the `present` function in the `ssh` state changed from `md5` to `sha256`.

Execution Module Changes

- Several functions in the `systemd` execution module have gained a `no_block` argument, which when set to `True` will use `--no-block` in the `systemctl` command.
- In the `solarisips` `pkg` module, the default value for the `refresh` argument to the `list_upgrades` function has been changed from `False` to `True`. This makes the function more consistent with all of the other `pkg` modules (The other `pkg.list_upgrades` functions all defaulted to `True`).
- The functions which handle masking in the `systemd` module have changed. These changes are described above alongside the information on the new states which have been added to manage masking of systemd units.
- The *pkg.list_repo_pkgs* function for yum/dnf-based distros has had its default output format changed. In prior releases, results would be organized by repository. Now, the default for each package will be a simple list of versions. To get the old behavior, pass `byrepo=True` to the function.
- A `pkg.list_repo_pkgs` function has been added for both *Debian/Ubuntu* and `Arch Linux`-based distros.
- The *system* module changed its return format from "HH:MM AM/PM" to "HH:MM:SS AM/PM" for *get_system_time*.

- The default for the `fingerprint_hash_type` option used in the *ssh* execution module changed from `md5` to `sha256`.

Proxy Module Changes

The *proxy_merge_grains_in_module* configuration variable introduced in 2016.3, has been changed, defaulting to `True`.

The connection with the remote device is kept alive by default, when the module implements the `alive` function and *proxy_keep_alive* is set to `True`. The polling interval is set using the *proxy_keep_alive_interval* option which defaults to 1 minute.

The developers are also able to use the *proxy_always_alive*, when designing a proxy module flexible enough to open the connection with the remote device only when required.

Wildcard Versions in `pkg.installed` States

- The *pkg.installed* state now supports wildcards in package versions, for the following platforms:
  - SUSE/openSUSE Leap/Thumbleweed
  - Debian/Ubuntu
  - RHEL/CentOS
  - Arch Linux

  This support also extends to any derivatives of these distros, which use the *aptpkg*, *yumpkg*, or `pacman` providers for the `pkg` virtual module.

  Using wildcards can be useful for packages where the release name is built into the version in some way, such as for RHEL/CentOS which typically has version numbers like `1.2.34-5.el7`. An example of the usage for this would be:

```
mypkg:
  pkg.installed:
    - version: '1.2.34*'
```

Master Configuration Additions

- *syndic_forward_all_events* - Option on multi-syndic or single when connected to multiple masters to be able to send events to all connected masters.
- *eauth_acl_module* - In case external auth is enabled master can get authenticate and get the authorization list from different auth modules.
- *keep_acl_in_token* - Option that allows master to build ACL once for each user being authenticated and keep it in the token.

Minion Configuration Additions

- *pillarenv_from_saltenv* - When set to `True` (default is `False`), the *pillarenv* option will take the same value as the effective saltenv when running states. This would allow a user to run `salt '*' state.apply mysls saltenv=dev`, and the SLS for both the state and pillar data would be sourced from the `dev` environment, essentially the equivalent of running `salt '*' state.apply mysls saltenv=dev` `pillarenv=dev`. Note that if *pillarenv* is set in the minion config file, or if `pillarenv` is provided on the CLI, it will override this option.

salt-api Changes

The `rest_cherrypy` netapi module has received a few minor improvements:

- A CORS bugfix.
- A new `/token` convenience endpoint to generate Salt eauth tokens.
- A proof-of-concept JavaScript single-page application intended to demonstrate how to use the Server-Sent Events stream in an application. It is available in a default install by visiting the `/app` URL in a browser.

Python API Changes

`expr_form` Deprecation

The *LocalClient*'s `expr_form` argument has been deprecated and renamed to `tgt_type`. This change was made due to numerous reports of confusion among community members, since the targeting method is published to minions as `tgt_type`, and appears as `tgt_type` in the job cache as well.

While `expr_form` will continue to be supported until the **2019.2.0** release cycle (two major releases after this one), those who are using the *LocalClient* (either directly, or implictly via a *netapi module*) are encouraged to update their code to use `tgt_type`.

`full_return` Argument in `LocalClient` and `RunnerClient`

An `full_return` argument has been added to the `cmd` and `cmd_sync` methods in `LocalClient` and `RunnerClient` which causes the return data structure to include job meta data such as `retcode`.

This is useful at the Python API:

```
>>> import salt.client
>>> client = salt.client.LocalClient()
>>> client.cmd('*', 'cmd.run', ['return 1'], full_return=True)
{'jerry': {'jid': '20170520151213898053', 'ret': '', 'retcode': 1}}
```

As well as from salt-api:

```
% curl -b /tmp/cookies.txt -sS http://localhost:8000 \
    -H 'Content-type: application/json' \
    -d '[{
        "client": "local",
        "tgt": "*",
        "fun": "cmd.run",
        "arg": ["return 1"],
        "full_return": true
    }]'

{"return": [{"jerry": {"jid": "20170520151531477653", "retcode": 1, "ret": ""}}]}
```

Logs

Another new feature - although not limited to Jinja only - is being able to log debug messages directly from the template:

```
{%- do salt.log.error('logging from jinja') -%}
```

See the *logs* paragraph.

Network Automation

NAPALM

Introduced in 2016.11, the modules for cross-vendor network automation have been improved, enhanced and widenened in scope:

- Manage network devices like servers: the NAPALM modules have been transformed so they can run in both proxy and regular minions. That means, if the operating system allows, the salt-minion package can be installed directly on the network gear. Examples of such devices (also covered by NAPALM) include: Arista, Cumulus, Cisco IOS-XR or Cisco Nexus.
- Not always alive: in certain less dynamic environments, maintaining the remote connection permanently open with the network device is not always beneficial. In those particular cases, the user can select to initialize the connection only when needed, by specifying the field `always_alive: false` in the *`proxy configuration`* or using the *`proxy_always_alive`* option.
- Proxy keepalive: due to external factors, the connection with the remote device can be dropped, e.g.: packet loss, idle time (no commands issued within a couple of minutes or seconds), or simply the device decides to kill the process. In 2017.7.0 we have introduced the functionality to re-establish the connection. One can disable this feature through the *`proxy_keep_alive`* option and adjust the polling frequency speciying a custom value for *`proxy_keep_alive_interval`*, in minutes.

New modules:

- *`Netconfig state module`* - Manage the configuration of network devices using arbitrary templates and the Salt-specific advanced templating methodologies.
- `Network ACL execution module` - Generate and load ACL (firewall) configuration on network devices.
- *`Network ACL state`* - Manage the firewall configuration. It only requires writing the pillar structure correctly!
- *`NAPALM YANG execution module`* - Parse, generate and load native device configuration in a standard way, using the OpenConfig/IETF models. This module contains also helpers for the states.
- `NAPALM YANG state module` - Manage the network device configuration according to the YANG models (OpenConfig or IETF).
- *`NET finder`* - Runner to find details easily and fast. It's smart enough to know what you are looking for. It will search in the details of the network interfaces, IP addresses, MAC address tables, ARP tables and LLDP neighbors.
- *`BGP finder`* - Runner to search BGP neighbors details.
- *`NAPALM syslog`* - Engine to import events from the napalm-logs library into the Salt event bus. The events are based on the syslog messages from the network devices and structured following the OpenConfig/IETF YANG models.
- `NAPALM Helpers` - Generic helpers for NAPALM-related operations. For example, the `Compliance report` function can be used inside the state modules to compare the expected and the existing configuration.

New functions:

- *`Configuration getter`* - Return the whole configuration of the network device.
- *`Optics getter`* - Fetches the power usage on the various transceivers installed on the network device (in dBm).

New grains: *`Host`*, *`Host DNS`*, *`Username`* and *`Optional args`*.

Custom Refspecs in GitFS / git_pillar / winrepo

It is now possible to specify the refspecs to use when fetching from remote repositories for GitFS, git_pillar, and winrepo. More information on how this feature works can be found *here* in the GitFS Walkthrough. The git_pillar and winrepo versions of this feature work the same as their GitFS counterpart.

git_pillar "mountpoints" Feature Added

See *here* for detailed documentation.

Big Improvements to Docker Support

The old `docker` state and execution modules have been moved to salt-contrib. The `dockerng` execution module has been renamed to `docker` and now serves as Salt's official Docker execution module.

The old `dockerng` state module has been split into 4 state modules:

- *`docker_container`* - States to manage Docker containers
- *`docker_image`* - States to manage Docker images
- *`docker_volume`* - States to manage Docker volumes
- *`docker_network`* - States to manage Docker networks

The reason for this change was to make states and requisites more clear. For example, imagine this SLS:

```
myuser/appimage:
  docker.image_present:
    - sls: docker.images.appimage

myapp:
  docker.running:
    - image: myuser/appimage
    - require:
      - docker: myuser/appimage
```

The new syntax would be:

```
myuser/appimage:
  docker_image.present:
    - sls: docker.images.appimage

myapp:
  docker_container.running:
    - image: myuser/appimage
    - require:
      - docker_image: myuser/appimage
```

This is similar to how Salt handles MySQL, MongoDB, Zabbix, and other cases where the same execution module is used to manage several different kinds of objects (users, databases, roles, etc.).

Note: With the Moby announcement coming at this year's DockerCon, Salt's *`docker`* execution module (as well as the state modules) work interchangeably when **docker** is replaced with **moby** (e.g. *`moby_container.running`*, *`moby_image.present`*, *`moby.inspect_container`*, etc.)

The old syntax will continue to work until the **2019.2.0** release of Salt. The old `dockerng` naming will also continue to work until that release, so no immediate changes need to be made to your SLS files (unless you were still using the old docker states that have been moved to salt-contrib).

The *`docker_container.running`* state has undergone a significant change in how it determines whether or not a container needs to be replaced. Rather than comparing individual arguments to their corresponding values in the named container, a temporary container is created (but not started) using the passed arguments. The two containers are then compared to each other to determine whether or not there are changes, and if so, the old container is stopped and destroyed, and the temporary container is renamed and started.

Salt still needs to translate arguments into the format which docker-py expects, but if it does not properly do so, the *skip_translate* argument can be used to skip input translation on an argument-by-argument basis, and you can then format your SLS file to pass the data in the format that the docker-py expects. This allows you to work around any changes in Docker's API or issues with the input translation, and continue to manage your Docker containers using Salt. Read the documentation for *skip_translate* for more information.

Note: When running the `docker_container.running` state for the first time after upgrading to 2017.7.0, your container(s) may be replaced. The changes may show diffs for certain parameters which say that the old value was an empty string, and the new value is `None`. This is due to the fact that in prior releases Salt was passing empty strings for these values when creating the container if they were undefined in the SLS file, where now Salt simply does not pass any arguments not explicitly defined in the SLS file. Subsequent runs of the state should not replace the container if the configuration remains unchanged.

New SSH Cache Roster

The `SSH cache Roster` has been rewritten from scratch to increase its usefulness. The new roster supports all minion matchers, so it is now possible to target minions identically through *salt* and *salt-ssh*.

Using the new `roster_order` configuration syntax it's now possible to compose a roster out of any combination of grains, pillar and mine data and even Salt SDB URLs. The new release is also fully IPv4 and IPv6 enabled and even has support for CIDR ranges.

Salt-SSH Default Options

Defaults for rosters can now be set, so that they don't have to be set on every entry in a roster or specified from the commandline.

The new option is `roster_defaults` and is specified in the master config file:

```
roster_defaults:
  user: daniel
  sudo: True
  priv: /root/.ssh/id_rsa
  tty: True
```

Blacklist or Whitelist Extmod Sync

The modules that are synced to minions can now be limited.

The following configuration options have been added for the master:

- `extmod_whitelist`
- `extmod_blacklist`

and for the minion:

- `extmod_whitelist`
- `extmod_blacklist`

Additional Features

- The *mine.update* function has a new optional argument `mine_functions` that can be used to refresh mine functions at a more specific interval than scheduled using the `mine_interval` option. However, this argument can be used by explicit schedule. For example, if we need the mines for `net.lldp` to be refreshed every 12 hours:

```
schedule:
  lldp_mine_update:
    function: mine.update
    kwargs:
      mine_functions:
        net.lldp: []
    hours: 12
```

- The `salt` runner has a new function: *salt.execute*. It is mainly a shortcut to facilitate the execution of various functions from other runners, e.g.:

```
ret1 = __salt__['salt.execute']('*', 'mod.fun')
```

New Modules

Beacons

- *salt.beacons.log*

Deprecations

General Deprecations

- Removed support for aliasing `cmd.run` to `cmd.shell`.
- Removed support for Dulwich from *GitFS*.
- Beacon configurations should be lists instead of dictionaries.
- The `PidfileMixin` has been removed. Please use `DaemonMixIn` instead.
- The `use_pending` argument was removed from the `salt.utils.event.get_event` function.
- The `pending_tags` argument was removed from the `salt.utils.event.get_event` function.

Configuration Option Deprecations

- The `client_acl` configuration option has been removed. Please use `publisher_acl` instead.
- The `client_acl_blacklist` configuration option has been removed. Please use `publisher_acl_blacklist` instead.
- The `win_gitrepos` configuration option has been removed. Please use the `winrepo_remotes` option instead.
- The `win_repo` configuration option has been removed. Please use `winrepo_dir` instead.
- The `win_repo_mastercachefile` configuration option has been removed. Please use the `winrepo_cachefile` option instead.

Module Deprecations

The `git` execution module had the following changes:

- The `fmt` argument was removed from the `archive` function. Please use `format` instead.
- The `repository` argument was removed from the `clone` function. Please use `url` instead.
- The `is_global` argument was removed from the `config_set` function. Please use `global` instead.
- The `branch` argument was removed from the `merge` function. Please use `rev` instead.

- The `branch` argument was removed from the `push` function. Please use `rev` instead.

The `glusterfs` execution module had the following functions removed:

- `create`: Please use `create_volume` instead.
- `delete`: Please use `delete_volume` instead.
- `list_peers`: Please use `peer_status` instead.

The `htpasswd` execution module had the following function removed:

- `useradd_all`: Please use `useradd` instead.

The `img` execution module has been removed. All of its associated functions were marked for removal in the 2017.7.0 release. The functions removed in this module are mapped as follows:

- `mount_image`/`mnt_image`: Please use `mount.mount` instead.
- `umount_image`: Please use `mount.umount` instead.
- `bootstrap`: Please use `genesis.bootstrap` instead.

The `smartos_virt` execution module had the following functions removed:

- `create`: Please use `start` instead.
- `destroy` Please use `stop` instead.
- `list_vms`: Please use `list_domains` instead.

The `virt` execution module had the following functions removed:

- `create`: Please use `start` instead.
- `destroy` Please use `stop` instead.
- `list_vms`: Please use `list_domains` instead.

The `virtualenv_mod` execution module had the following changes:

- The `package_or_requirement` argument was removed from both the `get_resource_path` and the `get_resource_content` functions. Please use `package` instead.
- The `resource_name` argument was removed from both the `get_resource_path` and `get_resource_content` functions. Please use `resource` instead.

The `win_repo` execution module had the following changes:

- The `win_repo_source_dir` option was removed from the `win_repo` module. Please use `winrepo_source_dir` instead.

The `xapi` execution module had the following functions removed:

- `create`: Please use `start` instead.
- `destroy`: Please use `stop` instead.
- `list_vms`: Please use `list_domains` instead.

The `zypper` execution module had the following function removed:

- `info`: Please use `info_available` instead.

Pillar Deprecations

- Support for the `raw_data` argument for the file_tree ext_pillar has been removed. Please use `keep_newline` instead.
- SQLite3 database connection configuration previously had keys under pillar. This legacy compatibility has been removed.

Proxy Minion Deprecations

- The `proxy_merge_grains_in_module` default has been switched from `False` to `True`.

Salt-API Deprecations

- The `SaltAPI.run()` function has been removed. Please use the `SaltAPI.start()` function instead.

Salt-Cloud Deprecations

- Support for using the keyword `provider` in salt-cloud provider config files has been removed. Please use `driver` instead. The `provider` keyword should now only be used in cloud profile config files.

Salt-SSH Deprecations

- The `wipe_ssh` option for `salt-ssh` has been removed. Please use the `ssh_wipe` option instead.

State Deprecations

The `apache_conf` state had the following functions removed:

- `disable`: Please use `disabled` instead.
- `enable`: Please use `enabled` instead.

The `apache_module` state had the following functions removed:

- `disable`: Please use `disabled` instead.
- `enable`: Please use `enabled` instead.

The `apache_site` state had the following functions removed:

- `disable`: Please use `disabled` instead.
- `enable`: Please use `enabled` instead.

The `chocolatey` state had the following functions removed:

- `install`: Please use `installed` instead.
- `uninstall`: Please use `uninstalled` instead.

The `git` state had the following changes:

- The `config` function was removed. Please use `config_set` instead.
- The `is_global` option was removed from the `config_set` function. Please use `global` instead.

- The `always_fetch` option was removed from the `latest` function, as it no longer has any effect. Please see the *2015.8.0* release notes for more information.
- The `force` option was removed from the `latest` function. Please use `force_clone` instead.
- The `remote_name` option was removed from the `latest` function. Please use `remote` instead.

The `glusterfs` state had the following function removed:

- `created`: Please use `volume_present` instead.

The `openvswitch_port` state had the following change:

- The `type` option was removed from the `present` function. Please use `tunnel_type` instead.

Security Fix

CVE-2017-12791 Maliciously crafted minion IDs can cause unwanted directory traversals on the Salt-master

Correct a flaw in minion id validation which could allow certain minions to authenticate to a master despite not having the correct credentials. To exploit the vulnerability, an attacker must create a salt-minion with an ID containing characters that will cause a directory traversal. Credit for discovering the security flaw goes to: Vernhk@qq.com

Windows Changes

`pkg` Execution Module'

Significate changes (PR #43708 & #45390, damon-atkins) have been made to the pkg execution module. Users should test this release against their existing package sls definition files.

- `pkg.list_available` no longer defaults to refreshing the winrepo meta database.

- *`pkg.install`* without a `version` parameter no longer upgrades software if the software is already installed. Use `pkg.install version=latest` (or simply use a *`pkg.latest`* state to get the old behavior.
- *`pkg.list_pkgs`* now returns multiple versions if software installed more than once.
- *`pkg.list_pkgs`* now returns `Not Found` when the version is not found instead of `(value not set)` which matches the contents of the sls definitions.
- *`pkg.remove`* will wait up to 3 seconds (normally about a second) to detect changes in the registry after removing software, improving reporting of version changes.
- *`pkg.remove`* can remove `latest` software, if `latest` is defined in sls definition.
- Documentation was update for the execution module to match the style in new versions, some corrections as well.
- All install/remove commands are prefix with cmd.exe shell and cmdmod is called with a command line string instead of a list. Some sls files in saltstack/salt-winrepo-ng expected the commands to be prefixed with cmd.exe (i.e. the use of &).
- Some execution module functions results, now behave more like their Unix/Linux versions.

`cmd` Execution Module

Due to a difference in how Python's `subprocess.Popen()` spawns processes on Windows, passing the command as a list of arguments can result in problems. This is because Windows' *CreateProcess* requires the command to be passed as a single string. Therefore, `subprocess` will attempt to re-assemble the list of arguments into as string. Some escaped characters and quotes can cause the resulting string to be incorrectly-assembled, resulting in a failure to execute the command.

Salt now deals with these cases by joining the list of arguments correctly and ensuring that the command is passed to `subprocess.Popen()` as a string.

  - 494835c3f2 I backported develop and applied a long list of fixes to 2016.11 this brings these fixes into 2017.7 - Software was not always being removed, general if & was in the string or msi was downloaded to uninstall the software - pkg.list_upgrades failed. Added support for 'latest' and 'Not Found' for version_cmp() to fix this. - output fixes - pkg.list_available no longer forces a pkg.refresh_db this is no longer required, as by default it will update if older than 6 hours - cmd /s /c is prefixed for all commands i.e. installs and removes. - cmd are now strings, instead of a list when using cmd.run. As windows only supports strings. And the " were being broken

Changes to `file.blockreplace` State

The `append_newline` argument was added to this state. Additionally, to improve idempotence, if the string represented by `marker_end` is found in the middle of the line, the content preceding the marker will be removed when the block is replaced. This allows one to remove `append_newline: False` from the SLS and have the block properly replaced if the end of the content block is immediately followed by the `marker_end` (i.e. no newline before the marker).

Note: This will require changes to your SLS if your `marker_end` does not include the very beginning of the content you want to keep.

See the *`file.blockreplace`* state documentation for further information.

Tornado 5.0 Support for Python 2 Only

Tornado 5.0 moves to using asyncio for all python3 versions. Because of this and changes in asyncio between python 3.4 and 3.5 to only be able to use one ioloop, which requires some rearchitecting, support for tornado 5.0 and python3 versions of salt has been delayed to a later release.

For now, to use tornado 5.0, the python 2 version of salt must be used.

Option to Return to Previous Pillar Include Behavior

Prior to version 2017.7.3, keys from *pillar includes* would be merged on top of the pillar SLS. Since 2017.7.3, the includes are merged together and then the pillar SLS is merged on top of that.

The `pillar_includes_override_sls` option has been added allow users to switch back to the pre-2017.7.3 behavior.

  - 152c43c843 Accounting for a case when multiple onfails are used along with requires. Previously if you have multiple states using 'onfail' and two of those states using a 'require' against the first one state, the last two will run even if the 'onfail' isn't met because the 'require' is met because the first state returns true even though it didn't excute. This change adds an additional hidden variable that is used when checking requisities to determine if the state actually ran.

28.2.27 Salt 2017.7.7 Release Notes

Version 2017.7.7 is a bugfix release for *2017.7.0*.

The `2017.7.7` release contains only a small number of fixes, which are detailed below.

This release fixes two critical issues.

The first is Issue #48038, which is a critical bug that occurs in a multi-syndic setup where the same job is run multiple times on a minion.

The second issue is #48130. This bug appears in certain setups where the Master reports a Minion time-out, even though the job is still running on the Minion.

Both of these issues have been fixed with this release.

28.2.28 Salt 2017.7.8 Release Notes

Version 2017.7.8 is a security and bugfix release for *2017.7.0*.

Security Fix

CVE-2018-15751 Remote command execution and incorrect access control when using salt-api.

CVE-2018-15750 Directory traversal vulnerability when using salt-api. Allows an attacker to determine what files exist on a server when querying /run or /events.

New win_snmp behavior

- *`win_snmp.get_community_names`* now returns the SNMP settings actually in effect on the box. If settings are managed via GroupPolicy, those settings will be returned. Otherwise, normal settings are returned.
- *`win_snmp.set_community_names`* now raises an error when SNMP settings are being managed by GroupPolicy.

Option Added to Disable Docker Mine Updates

When a docker container is added, removed, started, stopped, etc., the results of a `docker.ps verbose=True all=True host=True` are sent to the *mine*, to be used by *`mine.get_docker`*.

A new config option (*`docker.update_mine`*) has been added. When set to `False`, Salt will not send this information to the mine. This is useful in cases where sensitive information is stored in the container's environment.

- **PR** #48426: (garethgreenaway) [2017.7] fixes to states/pkg.py @ *2018-07-31 20:18:05 UTC*
  - 8a1285239a Merge pull request #48426 from garethgreenaway/46689_fixing_pkg_held_when_package_is_installed
  - 9b0f5dd212 Fixing identation, removing some unnecessary conditionals.
  - 727964ab55 One last cleanup.
  - 11cb86e6eb General cleanup in pkg state, reducing duplicate code. Fixing the requires_salt_modules decorator, sys.doc was returning too much information for the event to handle. This change specifically calls sys.doc with the module name.
  - 16fb6ae635 Make sure pkg.hold and pkg.unhold are available before running the test.
  - 998651102d Fixing a situation when a package is already installed via salt or manually and a state attempts to set that package to be held. Previously the holding/unholding logic was only being run against packages that were being installed. This change moves the holding logic outside and runs it against all desired packages. Adding a new test to test holding logic.

28.2.29 In Progress: Salt 2017.7.9 Release Notes

Version 2017.7.9 is an **unreleased** bugfix release for *2017.7.0*. This release is still in progress and has not been released yet.

Salt Cloud Features

GCE Driver

The GCE salt cloud driver can now be used with GCE instance credentials by setting the configuration paramaters `service_account_private_key` and `service_account_private_email` to an empty string.

28.2.30 Salt 2016.11.0 Release Notes - Codename Carbon

New Features

Docker Introspection and Configuration

Major additions have been made to the Docker support in 2016.11.0. The new addition allows Salt to be executed within a Docker container without a minion running or installed in the container. This allows states to be run inside a container, but also all of Salt's remote execution commands to be run inside docker containers as well. This makes container introspection simple and powerful. See the tutorial on using this new feature here:

See *Salt in Docker Containers*.

Advanced Ceph Control

Our friends over at SUSE have delivered a powerful new tool to make the deployment of Ceph storage systems using Salt very easy. These new Ceph tools allow for a storage system to be easily defined using the new *ceph.quorum* state.

Thorium Additions and Improvements

The Thorium advanced reactor has undergone extensive testing and updates. These updates include many more Thorium states, a system for automating key management, the ability to use Thorium to easily replace old reactors and a great deal of stability and bug fixes.

State Rollback Using Snapper

Rollback has been one of the most prevalent requests for Salt. We have researched it extensively and concluded that the only way to accomplish truly reliable rollback would be to execute it at the filesystem layer. To accomplish this we have introduced Snapper integration into Salt States.

Snapper is a tool which allows for simple and reliable snapshots of the filesystem to be made. With the new *snapper_states* option set to *True* in the minion config a snapshot will be made before and after every Salt State run.

These snapshots can be viewed, managed and rolled back to via the *snapper* execution module.

Preserve File Perms in File States

This feature has been requested for years, the ability to set a flag and use the same file permissions for files deployed to a minion as the permissions set to the file on the master. Just set the *keep_mode* option on any file management state to *True*.

Ponies!

We all agreed that cowsay was just not good enough, install the *ponysay* command and the new *pony* outputter will work. Fun for the whole family!

Additional Features

- Minions can run in stand-alone mode to use beacons and engines without having to connect to a master. (Thanks @adelcast!)
- Added a `salt` runner to allow running salt modules via salt-run.

  ```
  salt-run salt.cmd test.ping
  # call functions with arguments and keyword arguments
  salt-run salt.cmd test.arg 1 2 3 a=1
  ```

- Added SSL support to Cassandra CQL returner. SSL can be enabled by setting `ssl_options` for the returner. Also added support for specifying `protocol_version` when establishing cluster connection.
- The `mode` parameter in the *`file.managed`* state, and the `file_mode` parameter in the *`file.recurse`* state, can both now be set to `keep` and the minion will keep the mode of the file from the Salt fileserver. This

works only with files coming from sources prefixed with `salt://`, or files local to the minion (i.e. those which are absolute paths, or are prefixed with `file://`). For example:

```
/etc/myapp/myapp.conf:
  file.managed:
    - source: salt://conf/myapp/myapp.conf
    - mode: keep

/var/www/myapp:
  file.recurse:
    - source: salt://path/to/myapp
    - dir_mode: 755
    - file_mode: keep
```

- The `junos` state module is now available. It has all the functions that are present in the `junos` execution module.
- The `junos` state module is now available. It has all the functions that are present in the `junos` execution module.
- The minion data cache is a pluggable data store now. It's configurable with *`cache`* option. Default is `localfs`.
- User names in `client_acl` support glob matching now.

New Top File Merging Strategy for States

A new strategy called `merge_all` has been added to provide a new way of merging top file matches when executing a *highstate*. See the *`top_file_merging_strategy`* documentation for further information.

In addition, the `same` merging strategy was not functioning as documented. This has now been corrected. While this is technically a bugfix, we decided to hold a change in top file merging until a feature release to minimize user impact.

Improved Archive Extraction Support

The *`archive.extracted`* state has been overhauled. Notable changes include the following:

- When enforcing ownership (with the `user` and/or `group` arguments), the `if_missing` argument no longer has any connection to which path(s) have ownership enforced. Instead, the paths are determined using the either the newly-added *`archive.list`* function, or the newly-added `enforce_ownership_on` argument.
- `if_missing` also is no longer required to skip extraction, as Salt is now able to tell which paths would be present if the archive were extracted. It should, in most cases, only be necessary in cases where a semaphore file is used to conditionally skip extraction of the archive.
- Password-protected ZIP archives are now detected before extraction, and the state fails without attempting to extract the archive if no password was specified.
- By default, a single top-level directory is enforced, to guard against 'tar-bombs'. This enforcement can be disabled by setting `enforce_toplevel` to `False`.
- The `tar_options` and `zip_options` arguments have been deprecated in favor of a single `options` argument.
- The `archive_format` argument is now optional. The ending of the `source` argument is used to guess whether it is a tar, zip or rar file. If the `archive_format` cannot be guessed, then it will need to be specified, but in many cases it can now be omitted.

- Ownership enforcement is now performed irrespective of whether or not the archive needed to be extracted. This means that the state can be re-run after the archive has been fully extracted to repair changes to ownership.

A number of new arguments were also added. See the docs py:func:*docs for the archive.extracted state <salt.states.archive.extracted>* for more information.

Additionally, the following changes have been made to the `archive` execution module:

- A new function (`archive.list`) has been added. This function lists the files/directories in an archive file, and supports a `verbose` argument that gives a more detailed breakdown of which paths are files, which are directories, and which paths are at the top level of the archive.
- A new function (`archive.is_encrypted`) has been added. This function will return `True` if the archive is a password-protected ZIP file, `False` if not. If the archive is not a ZIP file, an error will be raised.
- `archive.cmd_unzip` now supports passing a password, bringing it to feature parity with `archive.unzip`. Note that this is still not considered to be secure, and `archive.unzip` is recommended for dealing with password-protected ZIP archives.
- The default value for the `extract_perms` argument to `archive.unzip` has been changed to `True`.

Improved Checksum Handling in `file.managed`, `archive.extracted` States

When the `source_hash` argument for these states refers to a file containing checksums, Salt now looks for checksums matching the name of the source URI, as well as the file being managed. Prior releases only looked for checksums matching the filename being managed. Additionally, a new argument (`source_hash_name`) has been added, which allows the user to disambiguate ambiguous matches when more than one matching checksum is found in the `source_hash` file.

A more detailed explanation of this functionality can be found in the `file.managed` documentation, in the section for the new `source_hash_name` argument.

Note: This improved functionality is also available in the `2016.3` (Boron) release cycle, starting with the 2016.3.5 release.

Config Changes

The following default config values were changed:

- `gitfs_ssl_verify`: Changed from `False` to `True`
- `git_pillar_ssl_verify`: Changed from `False` to `True`
- `winrepo_ssl_verify`: Changed from `False` to `True`

Grains Changes

- All core grains containing `VMWare` have been changed to `VMware`, which is the official capitalization. Additionally, all references to `VMWare` in the documentation have been changed to `VMware` issue #30807. Environments using versions of Salt before and after Salt 2016.11.0 should employ case-insensitive grain matching on these grains.

```
{% set on_vmware = grains['virtual'].lower() == 'vmware' %}
```

- On Windows the `cpu_model` grain has been changed to provide the actual cpu model name and not the cpu family.

  Old behavior:

  ```
  root@master:~# salt 'testwin200' grains.item cpu_model
  testwin200:
      ----------
      cpu_model:
          Intel64 Family 6 Model 58 Stepping 9, GenuineIntel
  ```

  New behavior:

  ```
  root@master:~# salt 'testwin200' grains.item cpu_model
  testwin200:
      ----------
      cpu_model:
          Intel(R) Core(TM) i7-3520M CPU @ 2.90GHz
  ```

Beacons Changes

- The `loadavg` beacon now outputs averages as integers instead of strings. (Via issue #31124.)

Runner Changes

- Runners can now call out to *utility modules* via `__utils__`.
- ref:*Utility modules <writing-utility-modules>* (placed in `salt://_utils/`) are now able to be synced to the master, making it easier to use them in custom runners. A *`saltutil.sync_utils`* function has been added to the *`saltutil runner`* to facilitate the syncing of utility modules to the master.

Pillar Changes

- Thanks to the new *`saltutil.sync_utils`* runner, it is now easier to get ref:*utility modules <writing-utility-modules>* synced to the correct location on the Master so that they are available in execution modules called from Pillar SLS files.

Junos Module Changes

- The following new functionalities were added to the junos module
  - facts - Displays the facts gathered during the connection.
  - shutdown - Shut down or reboot a device running Junos OS.
  - install_config - Modify the configuration of a Junos device.
  - install_os - Install Junos OS software package.
  - zeroize - Remove all configuration information on the Routing Engines and reset all key values on a device.
  - file_copy - Copy file from proxy to the Junos device.

Network Automation: NAPALM

Beginning with 2016.11.0, network automation is included by default in the core of Salt. It is based on a the NAPALM library and provides facilities to manage the configuration and retrieve data from network devices running widely used operating systems such: JunOS, IOS-XR, eOS, IOS, NX-OS etc.

- see the complete list of supported devices.

The connection is established via the *NAPALM proxy*.

In the current release, the following modules were included:

- *NAPALM grains* - Select network devices based on their characteristics
- *NET execution module* - Networking basic features
- *NTP execution module*
- *BGP execution module*
- *Routes execution module*
- *SNMP execution module*
- *Users execution module*
- *Probes execution module*
- *NTP peers management state*
- *SNMP configuration management state*
- *Users management state*

Cisco NXOS Proxy Minion

Beginning with 2016.11.0, there is a proxy minion that can be used to configure nxos cisco devices over ssh.

- *Proxy Minion*
- *Execution Module*
- *State Module*

Cisco Network Services Orchestrator Proxy Minion

Beginning with 2016.11.0, there is a proxy minion to use the Cisco Network Services Orchestrator as a proxy minion.

- *Proxy Minion*
- *Execution Module*
- *State Module*

Junos Module Changes

- The following new functionalities were added to the junos module
  - facts - Displays the facts gathered during the connection.
  - shutdown - Shut down or reboot a device running Junos OS.
  - install_config - Modify the configuration of a Junos device.

  - install_os - Install Junos OS software package.
  - zeroize - Remove all configuration information on the Routing Engines and reset all key values on a device.
  - file_copy - Copy file from proxy to the Junos device.

Returner Changes

- Any returner which implements a *save_load* function is now required to accept a *minions* keyword argument. All returners which ship with Salt have been modified to do so.

Renderer Changes

Added the ability to restrict allowed renderers. Two new config parameters, `renderer_whitelist` and `renderer_blacklist` are introduced for this purpose.

eAuth Changes

- External auth modules' `auth` method can return an ACL list for the given username instead of `True`. This list should be in the same format as described in the *eAuth documentation*. It will be used for the user instead of one set in master config.

  Example of the `auth` method return that allows a user to execute functions in the `test` and `network` modules on the minions that match the `web*` target and allow access to `wheel` and `runner` modules:

  ```
  [{'web*': ['test.*',
             'network.*']},
   '@wheel',
   '@runner']
  ```

- External auth is supported by *salt-run* and *salt-key* now. Note that master must be started to use them with eAuth.

External Module Packaging

Modules may now be packaged via entry-points in setuptools. See *external module packaging* tutorial for more information.

Functionality Changes

- The `onfail` requisite now uses OR logic instead of AND logic. issue #22370
- The consul external pillar now strips leading and trailing whitespace. issue #31165
- The win_system.py state is now case sensitive for computer names. Previously computer names set with a state were converted to all caps. If you have a state setting computer names with lower case letters in the name that has been applied, the computer name will be changed again to apply the case sensitive name.
- The `mac_user.list_groups` function in the `mac_user` execution module now lists all groups for the specified user, including groups beginning with an underscore. In previous releases, groups beginning with an underscore were excluded from the list of groups.
- The `junos.call_rpc` function in the `junos` execution module can now be used to call any valid rpc. Earlier it used to call only "get_software_information".

- A new option for minions called `master_tries` has been added. This specifies the number of times a minion should attempt to contact a master to attempt a connection. This allows better handling of occasional master downtime in a multi-master topology.
- The default hash_type is now sha256 instead of md5. You will need to make sure both your master and minion share the same hash_type.
- Nodegroups consisting of a simple list of minion IDs can now also be declared as a yaml list. The below two examples are equivalent:

```
# Traditional way
nodegroups:
  - group1: L@host1,host2,host3

# New way (optional)
nodegroups:
  - group1:
    - host1
    - host2
    - host3
```

New Azure ARM Cloud Driver

A new cloud driver has been added for Azure ARM, aka, the Azure Resource Manager. The older Azure driver is still required to work with the older Azure API. This new driver works with the newer ARM API, which is managed via the newer Azure Portal website.

Deprecations

General Deprecations

- `env` to `saltenv`

  All occurrences of `env` and some occurrences of `__env__` marked for deprecation in Salt 2016.11.0 have been removed. The new way to use the salt environment setting is with a variable called `saltenv`:

  ```
  def fcn(msg='', env='base', refresh=True, saltenv='base', **kwargs):
  ```

  has been changed to

  ```
  def fcn(msg='', refresh=True, saltenv='base', **kwargs):
  ```

  - If `env` (or `__env__`) is supplied as a keyword argument to a function that also accepts arbitrary keyword arguments, then a new warning informs the user that `env` is no longer used if it is found. This new warning will be removed in Salt 2017.7.0.

```
def fcn(msg='', refresh=True, saltenv='base', **kwargs):
```

```
# will result in a warning log message
fcn(msg='add more salt', env='prod', refresh=False)
```

  - If `env` (or `__env__`) is supplied as a keyword argument to a function that does not accept arbitrary keyword arguments, then python will issue an error.

```
def fcn(msg='', refresh=True, saltenv='base'):
```

```
# will result in a python TypeError
fcn(msg='add more salt', env='prod', refresh=False)
```

  - If `env` (or `__env__`) is supplied as a positional argument to a function, then undefined behavior will occur, as the removal of `env` and `__env__` from the function's argument list changes the function's signature.

```
def fcn(msg='', refresh=True, saltenv='base'):
```

```
# will result in refresh evaluating to True and saltenv likely not being a string at all
fcn('add more salt', 'prod', False)
```

- Deprecations in `minion.py`:
  - The `salt.minion.parse_args_and_kwargs` function has been removed. Please use the `salt.minion.load_args_and_kwargs` function instead.

Cloud Deprecations

- The `vsphere` cloud driver has been removed. Please use the `vmware` cloud driver instead.
- The `private_ip` option in the `linode` cloud driver is deprecated and has been removed. Use the `assign_private_ip` option instead.
- The `create_dns_record` and `delete_dns_record` functions are deprecated and have been removed from the `digital_ocean` driver. Use the `post_dns_record` function instead.

Execution Module Deprecations

- The `blockdev` execution module had four functions removed:
  - dump
  - tune
  - resize2fs
  - wipe

  The `disk` module should be used instead with the same function names.
- The `boto_vpc` execution module had two functions removed, `boto_vpc.associate_new_dhcp_options_to_vpc` and `boto_vpc.associate_new_network_acl_to_subnet` in favor of more concise function names, `boto_vpc.create_dhcp_options` and `boto_vpc.create_network_acl`, respectively.

- The `data` execution module had `getval` and `getvals` functions removed in favor of one function, `get`, which combines the functionality of the removed functions.
- File module deprecations:
    - The `contains_regex_multiline` function was removed. Use `file.search` instead.
    - Additional command line options for `file.grep` should be passed one at a time. Please do not pass more than one in a single argument.
- The `lxc` execution module has the following changes:
    - The `run_cmd` function was removed. Use `lxc.run` instead.
    - The `nic` argument was removed from the `lxc.init` function. Use `network_profile` instead.
    - The `clone` argument was removed from the `lxc.init` function. Use `clone_from` instead.
    - passwords passed to the `lxc.init` function will be assumed to be hashed, unless `password_encrypted=False`.
    - The `restart` argument for `lxc.start` was removed. Use `lxc.restart` instead.
    - The old style of defining lxc containers has been removed. Please use keys under which LXC profiles should be configured such as `lxc.container_profile.profile_name`.
- The `env` and `activate` keyword arguments have been removed from the `install` function in the `pip` execution module. The use of `bin_env` replaces both of these options.
- `reg` execution module

  Functions in the `reg` execution module had misleading and confusing names for dealing with the Windows registry. They failed to clearly differentiate between hives, keys, and name/value pairs. Keys were treated like value names. There was no way to delete a key.

  New functions were added in 2015.5 to properly work with the registry. They also made it possible to edit key default values as well as delete an entire key tree recursively. With the new functions in place, the following functions have been deprecated:

    - read_key
    - set_key
    - create_key
    - delete_key

  Use the following functions instead:

    - for `read_key` use `read_value`
    - for `set_key` use `set_value`
    - for `create_key` use `set_value` with no `vname` and no `vdata`
    - for `delete_key` use `delete_key_recursive`. To delete a value, use `delete_value`.
- The `hash_hostname` option was removed from the `salt.modules.ssh` execution module. The `hash_known_hosts` option should be used instead.
- The `human_readable` option was removed from the `uptime` function in the `status` execution module. The function was also updated in 2015.8.9 to return a more complete offering of uptime information, formatted as an easy-to-read dictionary. This updated function replaces the need for the `human_readable` option.
- The `persist` kwarg was removed from the `win_useradd` execution module. This option is no longer supported for Windows. `persist` is only supported as part of user management in UNIX/Linux.

- The `zpool_list` function in the `zpool` execution module was removed. Use `list` instead.

Outputter Module Deprecations

- The `compact` outputter has been removed. Set `state_verbose` to `False` instead.

Runner Module Deprecations

- The `grains.cache` runner no longer accepts `outputter` or `minion` as keyword arguments. Users will need to specify an outputter using the `--out` option. `tgt` is replacing the `minion` kwarg.
- The `fileserver` runner no longer accepts the `outputter` keyword argument. Users will need to specify an outputter using the `--out` option.
- The `jobs` runner no longer accepts the `outputter` keyword argument. Users will need to specify an outputter using the `--out` option.
- `virt` runner module:
  - The `hyper` kwarg was removed from the `init`, `list`, and `query` functions. Use the `host` option instead.
  - The `next_hyper` function was removed. Use the `next_host` function instead.
  - The `hyper_info` function was removed. Use the `host_info` function instead.

State Module Deprecations

- The `env` and `activate` keyword arguments were removed from the `installed` function in the `pip` state module. The use of `bin_env` replaces both of these options.
- `reg` state module

  The `reg` state module was modified to work with the new functions in the execution module. Some logic was left in the `reg.present` and the `reg.absent` functions to handle existing state files that used the final key in the name as the value name. That logic has been removed so you now must specify value name (`vname`) and, if needed, value data (`vdata`).

  For example, a state file that adds the version value/data pair to the Software\Salt key in the HKEY_LOCAL_MACHINE hive used to look like this:

  ```
  HKEY_LOCAL_MACHINE\\Software\\Salt\\version:
    reg.present:
      - value: 2016.3.1
  ```

  Now it should look like this:

  ```
  HKEY_LOCAL_MACHINE\\Software\\Salt
    reg.present:
      - vname: version
      - vdata: 2016.3.1
  ```

  A state file for removing the same value added above would have looked like this:

  ```
  HKEY_LOCAL_MACHINE\\Software\\Salt\\version:
    reg.absent:
  ```

Now it should look like this:

```
HKEY_LOCAL_MACHINE\\Software\\Salt
  reg.absent:
    - vname: version
```

This new structure is important as it allows salt to deal with key default values which was not possible before. If vname is not passed, salt will work with the default value for that hivekey.

Additionally, since you could only delete a value from a the state module, a new function (`key_absent`) has been added to allow you to delete a registry key and all subkeys and name/value pairs recursively. It uses the new `delete_key_recursive` function.

For additional information see the documentation for the `reg` execution and state modules.

- `lxc` state module: The following functions were removed from the `lxc` state module:
  - `created`: replaced by the `present` state.
  - `started`: replaced by the `running` state.
  - `cloned`: replaced by the `present` state. Use the `clone_from` argument to set the name of the clone source.
- The `hash_hostname` option was removed from the `salt.states.ssh_known_hosts` state. The `hash_known_hosts` option should be used instead.
- The `always` kwarg used in the `built` function of the `pkgbuild` state module was removed. Use `force` instead.

Utils Module Deprecations

- The use of `jid_dir` and `jid_load` were removed from the `salt.utils.jid`. `jid_dir` functionality for job_cache management was moved to the `local_cache` returner. `jid_load` data is now retrieved from the `master_job_cache`.
- `ip_in_subnet` function in `salt.utils.network.py` has been removed. Use the `in_subnet` function instead.
- The `iam` utils module had two functions removed: `salt.utils.iam.get_iam_region` and `salt.utils.iam.get_iam_metadata` in favor of the aws utils functions `salt.utils.aws.get_region_from_metadata` and `salt.utils.aws.creds`, respectively.

28.2.31 Salt 2016.11.1 Release Notes

Version 2016.11.1 is a bugfix release for *2016.11.0*.

28.2.32 Salt 2016.11.10 Release Notes

Version 2016.11.10 is a security release for *2016.11.0*.

Changes for v2016.11.9..v2016.11.10

Security Fix

CVE-2018-15751 Remote command execution and incorrect access control when using salt-api.

CVE-2018-15750 Directory traversal vulnerability when using salt-api. Allows an attacker to determine what files exist on a server when querying /run or /events.

Credit and thanks for discovery and responsible disclosure: nullbr4in, xcuter, koredge, loupos, blackcon, Naver Business Platform

28.2.33 Salt 2016.11.2 Release Notes

Version 2016.11.2 is a bugfix release for *2016.11.0*.

Security Fixes

CVE-2017-5192 local_batch client external authentication not respected

The `LocalClient.cmd_batch()` method client does not accept `external_auth` credentials and so access to it from salt-api has been removed for now. This vulnerability allows code execution for already-authenticated users and is only in effect when running salt-api as the `root` user.

CVE-2017-5200 Salt-api allows arbitrary command execution on a salt-master via Salt's ssh_client

Users of Salt-API and salt-ssh could execute a command on the salt master via a hole when both systems were enabled.

We recommend everyone upgrade to 2016.11.2 as soon as possible.

- **PR** #39153: (nicholasmhughes) Fix selinux.mode state config file handling @ *2017-02-06 18:37:34 UTC*
  - 30455079fe Merge pull request #39153 from nicholasmhughes/fix-selinux.mode-config-predictability
  - 8d8ba9c7d2 added the new getconfig function to the test
  - a6a24e1a1b Addressed edge case when attempting to set the config file to 'Disabled'. The state should only check the file, since the in-memory setting won't disappear until after reboot.
  - 6858658cc2 The selinux.mode state only checked the current status of SELinux in memory (getenforce) when determining if changes needed to be made. The /etc/selinux/config file could have a different value, and it would not be changed. This commit enhances idempotency of the state in regards to both the in-memory and configuration file enforcement of SELinux.

28.2.35 Salt 2016.11.4 Release Notes

Version 2016.11.4 is a bugfix release for *2016.11.0*.

AIX Support Expanded

AIX support has been added for the following execution modules:

- *`user`*
- *`group`*
- *`network`*
- *`status`*
- *`timezone`*

Additionally, AIX is now supported in the *`disk.iostat`* remote-execution function, and the *`status`* beacon is now supported.

Minion Data Cache Enhancement

Memcache is now supported as a data store for the minion data cache.

Memcache is an additional cache layer that keeps a limited amount of data fetched from the minion data cache for a limited period of time in memory that makes cache operations faster. It doesn't make much sense for the `localfs` cache driver but helps for more complex drivers like `consul`.

For more details see `memcache_expire_seconds` and other `memcache_*` options in the master config reverence.

Docker Fixes

- Docker authentication has been re-organized. Instead of attempting a login for each push/pull (which was unnecessary), a new function called `dockerng.login` has been added, which authenticates to the registry and adds the credential token to the `~/.docker/config.json`. After upgrading, if you have not already performed a `docker login` on the minion using the docker CLI, you will need to run `dockerng.login` to login. This only needs to be done once.
- A bug in resolving the tag name for images in a custom registry (where a colon can appear in the image name, e.g. `myregistry.com:5000/image:tagname`) has been fixed. In previous releases, Salt would use the colon to separate the tag name from the image name, and if there was no colon, the default tag name of `latest` would be assumed. However, this caused custom registry images to be misidentified when no explicit tag name was passed (e.g. `myregistry.com:5000/image`). To work around this in earlier releases, simply specify the tag name.

Salt-Cloud Fixes

2016.11.0 added support for templating userdata files for the `ec2` driver, using the `renderer` option from the master config file. However, as the default renderer first evaluates jinja templating, followed by loading the data as a YAML dictionary, this results in unpredictable results when userdata files are comprised of non-YAML data (which they generally are).

2016.11.4 fixes this by only templating the userdata_file when it is explicitly configured to do so. This is done by adding a new optional parameter to the cloud profile called `userdata_template`. This option is used in the same way as the `template` argument in `file.managed` states, it is simply set to the desired templating renderer:

```
my-ec2-config:
  # Pass userdata to the instance to be created
  userdata_file: /etc/salt/my-userdata-file
  userdata_template: jinja
```

If no `userdata_template` option is set in the cloud profile, then salt-cloud will check for the presence of the master configuration parameter `userdata_renderer`. If this is also not set, then no templating will be performed on the userdata_file.

In addition, the other cloud drivers which support setting a `userdata_file` (`azurearm`, `nova`, and `openstack`) have had templating support added to bring them to feature parity with the ec2 driver's implementation of the `userdata_file` option.

Patched Packages

Due to the critical nature of issue issue #41230 we have decided to patch the 2016.11.5 packages with PR #41244. This issue affects all calls to a salt-minion if there is an ipv6 nameserver set on the minion's host. The patched packages on repo.saltstack.com will divert from the v2016.11.5 tag and pypi packages due to the patches applied to the packages.

  - d9546c6283 Merge pull request #41599 from garethgreenaway/41540_fixes_to_archive_module
  - 66a136e6d8 Fixing issues raised in #41540 when a zip file is created on a Windows system. The issue has two parts, first directories that end up in the archive end up in the results of aarchive.list twice as they show up as both files and directories because of the logic to handle the fact that Windows doesn't mark them as directories. This issue shows up when an extraction is run a second time since the module verified the file types and the subdirectory is not a file. The second issue is related to permissions, if Salt is told to extract permissions (which is the default) then the directory and files end up being unreadable since the permissions are not available. This change sets the permissions to what the default umask for the user running Salt is.

28.2.38 Salt 2016.11.7 Release Notes

Version 2016.11.7 is a bugfix release for *2016.11.0*.

Security Fix

CVE-2017-12791 Maliciously crafted minion IDs can cause unwanted directory traversals on the Salt-master

This release corrects a flaw in minion ID validation which could allow certain minions to authenticate to a master despite not having the correct credentials. To exploit the vulnerability, an attacker must create a salt-minion with an ID containing characters that will cause a directory traversal. Credit for discovering the security flaw goes to: Vernhk@qq.com

28.2.39 Salt 2016.11.8 Release Notes

Version 2016.11.8 is a bugfix release for *2016.11.0*.

Security Fix

CVE-2017-14695 Directory traversal vulnerability in minion id validation in SaltStack. Allows remote minions with incorrect credentials to authenticate to a master via a crafted minion ID. Credit for discovering the security flaw goes to: Julian Brost (julian@0x4a42.net)

CVE-2017-14696 Remote Denial of Service with a specially crafted authentication request. Credit for discovering the security flaw goes to: Julian Brost (julian@0x4a42.net)

Anonymous Binds and LDAP/Active Directory

When `auth.ldap.anonymous` is set to `False`, the bind password can no longer be empty.

Windows Changes

`pkg` Execution Module‘

Significate changes (PR #43708 & #45390, damon-atkins) have been made to the pkg execution module. Users should test this release against their existing package sls definition files.

- *`pkg.list_available`* no longer defaults to refreshing the winrepo meta database.
- *`pkg.install`* without a `version` parameter no longer upgrades software if the software is already installed. Use `pkg.install version=latest` (or simply use a *`pkg.latest`* state to get the old behavior.
- *`pkg.list_pkgs`* now returns multiple versions if software installed more than once.
- *`pkg.list_pkgs`* now returns `Not Found` when the version is not found instead of `(value not set)` which matches the contents of the sls definitions.
- *`pkg.remove`* will wait up to 3 seconds (normally about a second) to detect changes in the registry after removing software, improving reporting of version changes.
- *`pkg.remove`* can remove `latest` software, if `latest` is defined in sls definition.
- Documentation was update for the execution module to match the style in new versions, some corrections as well.
- All install/remove commands are prefix with cmd.exe shell and cmdmod is called with a command line string instead of a list. Some sls files in saltstack/salt-winrepo-ng expected the commands to be prefixed with cmd.exe (i.e. the use of &).
- Some execution module functions results, now behave more like their Unix/Linux versions.

`cmd` Execution Module

Due to a difference in how Python's `subprocess.Popen()` spawns processes on Windows, passing the command as a list of arguments can result in problems. This is because Windows' *CreateProcess* requires the command to be passed as a single string. Therefore, `subprocess` will attempt to re-assemble the list of arguments into as string. Some escaped characters and quotes can cause the resulting string to be incorrectly-assembled, resulting in a failure to execute the command.

Salt now deals with these cases by joining the list of arguments correctly and ensuring that the command is passed to `subprocess.Popen()` as a string.

28.2.41 Salt 2016.3.0 Release Notes - Codename Boron

Known Issues

Warning: Some Salt Masters may need to apply a patch for Default Job Cache to prevent a possible crash

An issue exists that prevents the Salt master from cleaning the default job cache. This issue can cause an overconsumption of resources resulting in a crash. 2016.3.0 Salt masters should apply the patch in PR #33555. This issue will be addressed in 2016.3.1.

- issue #33516: When upgrading from 2015.8.10 to 2016.3.0 on centos7/redhat7 salt-minion must be restarted twice.
- issue #33517: SPM does not work on amazon linux 2015 in 2016.3.0.

Backwards-incompatible Changes

- The default path for the *`extension_modules`* master config option has been changed. Prior to this release, the location was a directory named `extmods` in the Salt cachedir. On most platforms, this would put the *`extension_modules`* directory in `/var/cache/salt/extmods`. It has been moved one directory down, into the master cachedir. On most platforms, this is `/var/cache/salt/master/extmods`. Most users won't have to worry about this, but those who have been manually placing custom runners into `/var/cache/salt/extmods/runners`, or outputters into `/var/cache/salt/extmods/output`, etc. will be affected by this. To transition, it is recommended not to simply move the extmods directory into `/var/cache/salt/master`, but to copy the custom modules into the salt fileserver under `salt://_runners`, `salt://_output`, etc. and sync them using the functions in the new *`saltutil runner`*.
- The `pkg.check_db` function has been removed for yum/dnf.

Core Changes

- The `onchanges` requisite now fires if **any** watched state changes. issue #19592.
- The `ext_pillar` functions **must** now accept a minion ID as the first argument. This stops the deprecation path started in Salt 0.17.x. Before this minion ID first argument was introduced, the minion ID could be retrieved accessing `__opts__['id']` losing the reference to the master ID initially set in opts. This is no longer the case, `__opts__['id']` will be kept as the master ID.
- Custom types can now be synced to the master using the new *`saltutil runner`*. Before, these needed to manually be placed under the *`extension_modules`* directory. This allows custom modules to easily be synced to the master to make them available when compiling Pillar data. Just place custom runners into `salt://_runners`, custom outputters into `salt://_output`, etc. and use the functions from the *`saltutil runner`* to sync them.
- The `client_acl` configuration options were renamed to `publisher_acl`.
- Added a new `--config-dump` option (issue #26639).
- TCP Transport presence events were updated to work with a NAT (PR #30629).

- A *minion_pillar_cache* setting was added to save rendered pillar data to cachedir for later use when file_client is set to local (PR #30428).
- Added the ability for binary data (such as a license key) to be distributed via pillar using the *file.managed* (issue #9569).
- Scheduled jobs now include `success` and `retcode` (issue #24237).
- The `saltversioninfo` grain was changed from a string to a list to enable reading values by index. (PR #30082).
- A *pillar_merge_lists* option was added to enable recursively merging pillar lists by aggregating them instead of replacing them (PR #30062).
- Grain values reported by Debian 8 (jessie) when lsb-release is installed were updated for consistency (PR #28649).
- A new option for minions called master_tries has been added. This specifies the number of times a minion should attempt to contact a master to attempt a connection. This allows better handling of occasional master downtime in a multi-master topology.
- The default directory for deploying the salt-thin tarball has changed for salt-ssh. It is now /var/tmp instead of /tmp. Users may also wish to delete any directories in /tmp ending with *_salt/*. (issue #32771)

External Module Packaging

Modules may now be packaged via entry-points in setuptools. See *external module packaging* tutorial for more information.

Cloud Changes

- Refactored the OpenNebula driver and added numerous `--function` and `--action` commands to enhance Salt support for image, template, security group, virtual network and virtual machine management in OpenNebula.
- Added execution/state modules to support the deployment of AWS cognito identity pools (PR #31094).
- Added ability to set tags and listener policies on a AWS ELB (PR #27552).

Platform Changes

- Renamed modules related to macOS. The following module filenames were changed. The virtual name remained unchanged.
- PR ##30558: renamed osxdesktop.py to mac_desktop.py
- PR ##30557: renamed macports.py to mac_ports.py
- PR ##30556: renamed darwin_sysctl.py to mac_sysctl.py
- PR ##30555: renamed brew.py to mac_brew.py
- PR ##30552: renamed darwin_pkgutil.py to mac_pkgutil.py

Package Support

- Ubuntu Xenial: Packages for Ubuntu Xenial (16.04) are available for 2016.3.0 and onwards. See repo.saltstack.com for more information. Note that Xenial comes with Debian's packaged version of Salt 2015.8.8 and official repo.saltstack.com packages are available for 2015.8 releases beginning with Salt 2015.8.11.

Proxy Minion Changes

The deprecated config option `enumerate_proxy_minions` has been removed.

As mentioned in earlier documentation, the `add_proxymodule_to_opts` configuration variable defaults to `False` in this release. This means if you have proxymodules or other code looking in `__opts__['proxymodule']` you will need to set this variable in your `/etc/salt/proxy` file, or modify your code to use the *__proxy__* injected variable.

The `__proxyenabled__` directive now only applies to grains and proxy modules themselves. Standard execution modules and state modules are not prevented from loading for proxy minions.

Support has been added to Salt's loader allowing custom proxymodules to be placed in `salt://_proxy`. Proxy minions that need these modules will need to be restarted to pick up any changes. A corresponding utility function, `saltutil.sync_proxymodules`, has been added to sync these modules to minions.

Enhancements in grains processing have made the `__proxyenabled__` directive somewhat redundant in dynamic grains code. It is still required, but best practices for the `__virtual__` function in grains files have changed. It is now recommended that the `__virtual__` functions check to make sure they are being loaded for the correct proxytype, example below:

```
def __virtual__():
    '''
    Only work on proxy
    '''
    try:
        if salt.utils.is_proxy() and \
           __opts__['proxy']['proxytype'] == 'ssh_sample':
            return __virtualname__
    except KeyError:
        pass

    return False
```

Note: `salt.utils.is_proxy()` has been renamed to `salt.utils.platform.is_proxy` as of the Oxygen release.

The try/except block above exists because grains are processed very early in the proxy minion startup process, sometimes earlier than the proxy key in the `__opts__` dictionary is populated.

Grains are loaded so early in startup that no dunder dictionaries are present, so `__proxy__`, `__salt__`, etc. are not available. Custom grains located in `/srv/salt/_grains` and in the salt install grains directory can now take a single argument, `proxy`, that is identical to `__proxy__`. This enables patterns like

```
def get_ip(proxy):
    '''
    Ask the remote device what IP it has
    '''
    return {'ip':proxy['proxymodulename.get_ip']()}
```

Then the grain `ip` will contain the result of calling the `get_ip()` function in the proxymodule called `proxymodulename`.

Proxy modules now benefit from including a function called `initialized()`. This function should return `True` if the proxy's `init()` function has been successfully called. This is needed to make grains processing easier.

Finally, if there is a function called `grains` in the proxymodule, it will be executed on proxy-minion startup and its contents will be merged with the rest of the proxy's grains. Since older proxy-minions might have used other methods to call such a function and add its results to grains, this is config-gated by a new proxy configuration option called `proxy_merge_grains_in_module`. This defaults to `False` in this release. It will default to True in the release after next. The next release is codenamed **Carbon**, the following is **Nitrogen**.

The example proxy minions `rest_sample` and `ssh_sample` have been updated to reflect these changes.

Syndic Updates

A major performance and management issue was found and fixed in the syndic. This makes the Salt Syndic substantially more reliable and performant. Please make sure that the syndic and the master of masters which syndics attach to are updated, otherwise the syndic fixes alone can cause minor performance issues with older master of masters. Please update masters first, then syndics. Minions do not need to be updated for this fix to work.

Module Changes

- *`file execution module`*: `show_diff` is deprecated in favor of `show_changes`. (PR #30988)
- *`reg execution module`*:
  - Removed the following deprecated functions from the reg module (PR #30956):
    - read_key
    - set_key
    - create_key
    - delete_key
  - Removed force parameter from reg state module
  - Fixed virtual function in state
  - Improved error information for `reg.delete_value` function
- *`jboss7 execution module`*: `deployed` function was decoupled from Artifactory by removing Artifactory-specific functionality. Note that the changes in some of the function arguments break existing state files, see issue #30515 and PR #3080 for details.
- *`pkg state module`*: The `wait` function was removed, the functionality was replaced with the `onchanges` requisite (PR #30297).
- *`firewalld state module`*: A `permanent` argument was added `add_port`. Note that `permanent` defaults to `True`, which changes previous behavior (PR #30275). A `bind` function was also added that allows binding zones to interfaces and sources (PR #29497).
- *`journald beacon module`*: The event string was updated to include a tag. Note this might impact existing reactors based on this beacon. (PR #30116).
- *`postgres_privileges state module`*: The default value of the `prepend` argument was changed from `None` to `public`.
- *`zenoss execution module`*: The `add_device` function was updated with a default value of `1000` for `prod_state` to match the documentation (PR #28924).

- The etcd execution module, state module, returner module, and util module were refactor (PR #28599). This refactor changes error returns for several functions (primarily edge cases):
  - get: Used to return " on key-not-found. Now returns None.
  - set: Used to return " on issues setting keys. Now returns None.
  - ls: Used to return {path: {}} on key-not-found. Now returns None.
  - Tree: Used to return {} on key-not-found. Now returns None.
- *smartos_virt execution module*: Updated to use most of the new smartos_vmadm (PR #28284).
- *apache_conf state module*, *apache_module state module*, and *apache_site state module*: the `enable` and `disable` functions were renamed to `enabled` and `disabled`, respectively. In PR #33562, these functions were readded and properly deprecated and will be removed in Salt 2017.7.0. This fix will be available in 2016.3.1. As a workaround, try

```
apache_module.enable{{ 'd' if grains.saltversioninfo == [2016, 3, 0] else '' }}
```

New Features

Thorium - Provisional New Reactor

The 2016.3 release introduces the new Thorium Reactor. This reactor is an experimental new feature that implements a flow programming interface using the salt state system as the engine. This means that the Thorium reactor uses a classic state tree approach to create a reactor that can aggregate event data from multiple sources and make aggregate decisions about executing reactions.

This feature is both experimental and provisional, it may be removed and APIs may be changed. This system should be considered as ambitious as the Salt State System in that the scope of adding a programmable logic engine of this scale into the event systems is non trivial.

See *Thorium Complex Reactor*.

Improved Mac OS Support

Improved Solaris Support

A lot of work was done to improve support for SmartOS. This work also resulted in improvements for Solaris and illumos as SmartOS.

- rewrite of *vmadm module* (SmartOS)
- rewrite of *imgadm module* (SmartOS)
- deprecation of *virt module* in favor of vmadm (SmartOS)
- implemented *smartos state* (SmartOS)
- improved *zpool module* add SmartOS, illumos and Solaris support
- improved *zfs module* add SmartOS, illumos and Solaris support
- implemented *zpool state*
- implemented *zfs state* implemented *solaris_system* system module to provide better Solaris support (PR #30519)
- other minor fixes to grains, localmod, ...

Tornado Transport

Important: The Tornado Transport wire protocol was changed in 2016.3, making it incompatible with 2015.8 (PR #29339).

Windows DSC Integration (Experiemental)

Dimension Data Cloud Support

A SaltStack Cloud driver for Dimension Data Public Cloud, provides the driver functionality to service automation for any of the Dimension Data Public Cloud locations:

- Deploy new virtual machines
- List and query virtual machine images
- Destroy and query virtual machines

Documentation of the Dimension Data SaltStack integration is found on developer.dimensiondata.com

Minion Blackout

During a blackout, minions will not execute any remote execution commands, except for *`saltutil.refresh_pillar`*. Blackouts are enabled using a special pillar key, `minion_blackout` set to `True`.

See *Minion Blackout*.

Splunk Returner

A Splunk Returner that uses HTTP Event Collector is now available (PR #30718).

SQLCipher Pillar Module

Support was added for retrieving pillar data via queries to SQLCiper databases (PR #29782).

Final Release of Debian 7 Packages

Regular security support for Debian 7 ended on April 25th, 2016. As a result, 2016.3.1 and 2015.8.10 will be the last Salt releases for which Debian 7 packages are created.

Known Issues

issue #36055: Salt Cloud events (`salt/cloud`) are not generated on the master event bus when provisioning cloud systems.

Bootstrap Issue #973: `python-futures` is not installed when installing from a git tag on RedHat-based distributions. `Python futures` is needed when

running Salt with the TCP transport. This is fixed on the `develop` branch of the salt-bootstrap repo and the fix will be included in the upcoming release of salt-bootstrap, but is a bug in the bootstrap release that ships with this version of Salt. Please see the salt-bootstrap repo for more information on how to update your bootstrap version.

Known Issues

The Salt Minion does not clean up files in `/tmp` when rendering templates. This potentially results in either running out of disk space or running out of inodes. Please see issue #37541 for more information. This bug was fixed with PR #37540, which will be available in the `2016.3.5` release of Salt.

The release of the `bootstrap-salt.sh` script that is included with 2016.3.4 release has a bug in it that fails to install salt correctly for git installs using tags in the 2015.5 branch. This bug has not been fixed in the salt-bootstrap repository yet, but the previous bootstrap release (v2016.08.16) does not contain this bug.

Changes

- The *disk.wipe* execution module function has been modified so that it correctly wipes a disk.
- Add ability to clone from a snapshot to the VMWare salt-cloud driver.
- Add ability to specify disk backing mode in the VMWare salt cloud profile.

Security Fixes

CVE-2017-5192 local_batch client external authentication not respected

The `LocalClient.cmd_batch()` method client does not accept `external_auth` credentials and so access to it from salt-api has been removed for now. This vulnerability allows code execution for already-authenticated users and is only in effect when running salt-api as the `root` user.

CVE-2017-5200 Salt-api allows arbitrary command execution on a salt-master via Salt's ssh_client

Users of Salt-API and salt-ssh could execute a command on the salt master via a hole when both systems were enabled.

We recommend everyone on the 2016.3 branch upgrade to a patched release as soon as possible.

Improved Checksum Handling in `file.managed`, `archive.extracted` States

When the `source_hash` argument for these states refers to a file containing checksums, Salt now looks for checksums matching the name of the source URI, as well as the file being managed. Prior releases only looked for checksums matching the filename being managed. Additionally, a new argument (`source_hash_name`) has been added, which allows the user to disambiguate ambiguous matches when more than one matching checksum is found in the `source_hash` file.

A more detailed explanation of this functionality can be found in the *file.managed* documentation, in the section for the new `source_hash_name` argument.
